ON

DIET AND REGIMEN:

BEING

A SYSTEMATIC INQUIRY

INTO THE MOST RATIONAL MEANS OF PRESERVING HEALTH AND PROLONGING LIFE:

TOGETHER WITH

PHYSIOLOGICAL AND CHEMICAL EXPLANATIONS,

CALCULATED CHIEFLY

FOR THE USE OF FAMILIES,

IN ORDER TO BANISH THE PREVAILING ABUSES AND PREJUDICES IN MEDICINE.

BY A. F. M. WILLICH, M. D.

Qui stomachum regem totius corporis esse Contendunt, vera niti ratione videntur: Hujus enim validus tenor sirmat omnia membra; At contrà ejusdem franguntur cuncta dolore.

Serenus Sammonicus, De Medicina Pracepta saluberrima.

Vol. I.

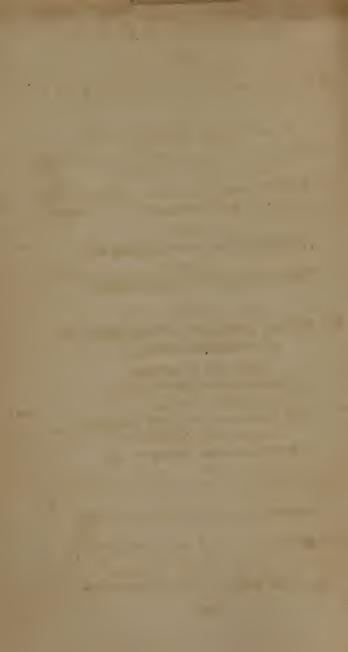

56047

The fird Bolton, from the Second London, Edition.

Correlled and improved, with considerable Additions.

BOSTON:

PRINTED BY MANNING & LORING,
FOR JOSEPH NANCREDE, No. 49, Marlbro'-Street.

THIS WORK

IS DEDICATED,

TO THOSE MOTHERS AND GUARDIANS OF FAMILIES,

WHOSE

GREATEST PRIDE AND HAPPINESS IT IS,

TO REAR

HEALTHY AND VIRTUOUS CHILDREN;

AND

TO THOSE FRIENDS OF SOCIETY AND THEMSELVES,

WHO ARE SOLICITOUS
TO PRESERVE THEIR HEALTH,
AND TO ADOPT
THE PARENTAL HINTS OF NATURE,
RATHER THAN SUBMIT TO
THE PALLIATIVE RELIEF OF ART.

ADVERTISEMENT TO THE BOSTON EDITION.

TO prevent disease by so simple and intelligible an expedient, as a due attention to Diet and Regimen, should become the most universal as it surely is the most rational pursuit of every man who values health, and is desirous of prolonging life. A judicious book, calculated to affist him in that pursuit, is therefore entitled to preeminence in every

man's library.

Books are not wanting which profess to teach us how to become our own physicians, when we are fick :- Indeed were we to credit implicitly the numerous nostrums and specifics, fo strongly commended by many writers on medical fubjects, we might almost venture to question the ordinary principle of human infirmity, or man's mortality. Authors of that description have given great encouragement to art, by discountenancing the suggestions of nature; and have furnished the means of creating diseases, instead of assisting in the purpose of cure or prevention. Before the prefent, no author had expressly undertaken to instruct mankind in the faculty of fhunning disease by means so simple as the regulation of Diet. This omission has probably been owing to an opinion, that the fubject is too trivial and ordinary to authorize

grave discussion, and that a man must first be acquainted minutely with the animal functions, before he should hazard an attempt to preserve them in order, or to rectify their derangements. The fallacy of fuch an opinion is most clearly exposed in the present production; and we may here be convinced, that the best and most effectual means of prolonging life, and fecuring the bleffings of health, are not only comprehenfible, without the aid of great investigation, but practicable without the necessity of great inconvenience or restraint. The rules contained in the present volumes are deduced from the most simple and obvious view of the fubject; and although they may exhibit nothing very myf-terious or abstruce, we presume they are not therefore entitled to less credit or attention. In these sentiments, we would not be considered to doubt the profundity of the healing art; we only admire the simplicity of our author's plan, for rendering the intervention of that art superfluous and unnecessary.

It is true, indeed, the brute creation have no factitious guide to direct them in the performance of their animal office; but nature, their only monitor, hath long fince ceased to be the guide of man. She forfook him when he abandoned her, to pursue the enjoyments of society, on the road of excess and intem-

perance.

In the present highly improved state of society, when the efforts of talents are on the stretch, to discover new pleasures, new

gratifications, it is not furprifing that the line of fober enjoyment should be overlooked.* Custom fortifies itself by appetites; it therefore requires no small degree of sagacity to discern, and sirmness to abstain from those excesses, where reason, already seduced by the allurement of new dainties, readily yields to the fascinating form in which they are presented to our senses. If it be an object of magnitude to correct the present perverted taste of mankind, and to revest pain with the power of self-defence, against a numerous train of mere artissicial maladies, then may we venture to declare, that this work is justly entitled to more encomiums than we have faculty

* Much time, learning, and talent has been bestowed on the researches, made into the causes of the late epidemic or endemic, or contagious fever, which has for a few years past desolated the capitals of the United States. Hypothefes were broached, opinions formed, parties raifed, but no cause found. What would the American faculty think, if, after so many inquiries, this mighty cause should be found resolvable in the vicious diet and incautious regimen peculiar to the Americans? Such are however the grounds of a very judicious treatife, written in French, and fent to the Prefident of the United States, that he might render it public. The author, who has refided feveral years in America, paints in firong colours the abufes of American dict, compares it minutely with the mode of living of other nations, especially those who live in the fame latitudes, attributes all the autumnal difeafes of the Americans, and namely their yellow fever, to that cause; and is furprifed that it does not produce still greater and more frequent evils, in the capitals of America, where the abufe cannot be excceded. Nor is the conclusion rash, when we find all foreigners, who vilit this country, Frenchmen, Germans, and even Englishmen, exclaiming against our copious and everlafting dinners. feasts and sumptuous entertainments are unknown in Europe, at which the rules of fobriety are trampled upon, but they are given on particular occasions only, whereas the ordinary of an American is an every day feaft. Americans who have travelled abroad, know the truth of this observation. To include in a party, where excess must follow, once or twice a month, may hurt us; but to overload the stomach every day, must kill us in a very short time.

to bestow. Our Author, unlike many others of his profession, seems to have been less desirous to discover the occult properties of the various articles of sustenance, than to determine their effects, when applied to the human constitution.

It is, moreover, a circumstance, adding not a little to the value and utility of these volumes, that they are furnished with a minute and copious index, referring particularly to almost every substance, vegetable or animal, in use among men, so that the reader may discover, almost by a single glance, the best rules by which to control his appetite, and the precise limits within which the inclination of his senses may be indulged with impunity.

Analytical TABLE of Contents.

VOLUME FIRST.

Y	Page
INTRODUCTION	I
State of Medicine, as a Science founded on facts	i3.
Observations on the general laws of Nature	4
Necessity of applying to the study of natural causes	5
Difference of opinions on medical subjects .	5 6
The origin and causes of diseases investigated	9
Cow-pox, a preventive of the Small-pox -	13
Remarks illustrating the doctrine of temperaments	14.
The absurdity and dangerous tendency of Patent or	
Quack Medicines pointed out -	22
Mr. James Parkinson, on Quack Medicines -	24
The nature of fashionable complaints defined	30
The fource of them investigated	31
The function of the skin explained	34
The necessity of bathing inculcated, as the best sub-	
stitute for universal remedies	41
The nature and properties of Cosmetics examined	43
The only effectual substitutes for them recommended,	
and injunctions relative to the improvement of	
the skin	46
Strictures on the physical education of children	49
Frequent bathing, an useful practice in infancy	53
The proper temperature of the Bath, and its general	
effects	ik.
The cold Bath frequently dangerous to children	ib.
The lukewarm or tepid Bath far preferable	ib.
Directions to use this Bath with advantage .	56
The utility of the Air Bath pointed out -	57
Shortness of Sight and weakness of the Eyes	58
Importance of spacious nurseries, and airing -	59
Huteland's picture of a child properly managed, with	
respect to washing, airing, and bathing	60
Ancedote of a Kushan postillion	62
Feather-beds and cumbersome Dresses condemned	63
The origin of a fweating Skin	ib.
A proper Couch for Children described -	- 64
Cleanliness, a cardinal virtue in domestic life	ib.

	age
Rickets, cured by cleanliness alone	64
How the head and breast should be covered -	65
Hiltorical anecdote from He odotus	ib.
Sudden improvements not successful	66
There is no perfect and permanent state of health	68
Quotation from Cicero	
Quotation from Ciccio	ib.
CHAP. I. On the Means of preserving Health	
and prolonging Life	69
	09
Definition of a good state of health	ib.
Reasons for being satisfied with our present state -	70
To avoid or cure diseases, we ought to be acquainted	
with the economy of the human frame	ib.
The pretended purpose of Nostrums explained	71
Man has always more or less valued a long life	ib.
The method of prolonging life adopted by the Orientals	72
The same plan prescribed by Boerhaave	
The inefficacy of it demonstrated	73
The Egyptians resorted to Sudorifics and Emetics	74
The Greeks employed natural means	76
The great advantage of Gymnastic Exercises considered	77
Modern methods of bracing the body	78
Excellence of the Grecian method	80
Plutarch's golden angeonts	ib.
Plutarch's golden precepts	81
Review of the barbarity of the middle ages	82
The Alchemists in search of original matter	83
The Tincture of Gold introduced	84
Sketch of the Goldmakers, Rosencrucians, &c.	85
Productions of Alchemy shorten life	87
They impair the fusceptibility, or power of receiving	- '
vitat juppites	88
Theophrastus Paracelsus, an insurer of lives	ib.
The world of spirits is summoned to a fig.	89
The protestors of Astrology begin their impositions	
and noted I nurnellen appears at Rarlin	90
Expolition of that occult science. A strology	91
Cornaro shows the absurdity of reforting to supernat-	16.
ural means, by his illustrious example	
Bloodletting came into general use	94
In what cases Venesection may be of advantage	98
Definition of the Art of prolonging Life	001
The nature of the Blood investigated	ib.

LECTURES

ON

DIET AND REGIMEN.

INTRODUCTION.

On the present State of Medicine as a Science.

E apparently live in an age, when every branch of human knowledge is reduced to a popular fystem; when the most important sciences lay aside the garb of pedantry and mysticisin; when, in short, the sources of information are open to every rank, and to both sexes. An improvement, which is so conspicuous, must ultimately be attended with the most desirable and extensive effects.

Among other beneficial pursuits to render the comforts of life more numerous and permanent, we have occasion to observe, that Natural Philosophy and Chemistry contribute a principal share in spreading useful knowl-

edge among all ranks of fociety.

Since Medicine, confidered as a science, which rests upon practical rules of experience, is in a great measure founded upon Natural Philosophy and Chemistry, it will be allowed that with the daily progress of the latter, Medicine also must necessarily partake

B

of their improvements, and continually receive accessions conducive to its further perfection.

With the progressive increase of refinement and luxury, a certain weakness and indisposition, whether real or imaginary, has infested society in the character of a gentle epidemic. It cannot properly be called a discase, but rather an approximation to an infirm state, which almost involuntarily compels man to reslect upon the relative situation of his physical nature, to acquire correct ideas on health, disease, and the means of prevention or relief, and thus imperceptibly to become his own guide.

Every individual of any penetration now claims the privilege of being his own physician: It is not unfashionable to form a certain system concerning the state of our own health, and to consider it as the criterion, by which we may judge of ourselves and others, of patients

and their physicians.

Formerly, people were not accustomed to think of the physical state of their body, until it began to be afflicted with pain or debility: In which case, they intrusted it to the practitioner in Physic, as we deliver a time-piece to a watchmaker, who repairs it according to the best of his knowledge, without apprehending, that its owner will be at the trouble of thinking or reasoning upon the method, which he judged to be most proper.

In our times, we frequently undertake the charge of prescribing medicines for ourselves:

And the natural confequence is, that we feldom are able to tell, whether we are healthy or difeafed; that we trust as much, if not more, to ourselves than to the physician, who is only fent for occasionally; and that we cannot conceive him to be perfectly free from the fystems of the schools, from self-interest or professional motives. Thus, by an acquaintance with medical subjects, which of itself is laudable, not only the skill of the physician is frequently thwarted, but the recovery of the patient unhappily retarded, or at least rendered more difficult.

No disease is now cured without demon-Aration; and he who can neither discover nor comply with the peculiar fystem of health adopted by his patient, may indeed act from motives dictated by reason and humanity; but his fuccess as a practical physician, in the common acceptation of that phrase, must ever remain problematical. Yet this general prot penfity to investigate medical subjects, if it were properly directed and gratified might be attended with very happy effects. For the medical art ought not to be subject to an inperious and fascinating demon, whose labours are chiefly carried on in the dark recesses of mystery, whom we know only from his baneful influence, as he spares no objects of prey, and holds his votaries in a perpetual state of dependence!

"The veil of mystery," says a modern popular writer, "which still hangs over Medicine, renders it not only a conjectural, but even a suspicious art. This has been long ago removed from the other sciences, which induces many to believe, that Medicine is a mere trick, and that it will not bear a fair and candid examination. Medicine, however, needs only to be better known, in order to secure the general esteem of mankind. Its precepts are such as every wise man would choose to observe, and it forbids nothing but what is incompatible with true happiness."

Observations on the general Laws of Nature.

If we reflect upon the admirable uniformity which prevails through the works of nature, both in the production and dissolution of matter, we find that the invariably moves in a circle; that in the perpetual construction, as well as in the fubsequent demolition of bodies, she is always equally new and equally perfect; that the fmallest particle, though invisible to our eyes, is usefully employed by her reftless activity; that death itself, or the destruction of forms and figures, is no more than a careful decomposition and a defigned regeneration of individual parts, in order to produce new fubstances, in a manner no less skilful than surprising. We further observe, that in the immense variety of things, in the inconceivable waste of elementary particles, there nevertheless prevails the firictest economy; that nothing is produced in vain, nothing confumed without a cause. We clearly perceive that all nature is united

by indiffoluble ties; that every thing exists for the fake of another, and that no one thing can exist without its neighbour. Hence we justly conclude, that man himself is not an insulated being, but that he is a necessary link in the great chain, which connects the universe.

Nature is our fafest guide, and she will be so with greater certainty, as we become better acquainted with her operations, especially with respect to those particulars which more nearly concern our physical existence. Thus, a source of many and extensive advantages will be opened; thus we shall approach to our original destination—namely, that of living

long and healthy...

On the contrary, as long as we move in a limited sphere of knowledge; as long as we are unconcerned with respect to the causes which produce health or disease, we are in danger; either of being anxiously parsimonious, or prodigally profuse of those powers, by which life is supported. Both extremes are contrary to the purpose of nature. She reaches us the rule of just economy:—we, being a small part of her great system, must follow her example, and expend neither too much nor too little of her treasures.

Although it be true that our knowledge of nature is still very imperfect, yet this circumstance ought not to deter us from investigating the means which may lead to its im-

provement.

We are affilted by the experience of fomany industrious inquirers, of so many sound philosophers, that we may flatter ourselves with the hopes of discovering some of her hidden secrets, and of penetrating still further into her wonderful recesses. This, however, cannot be accomplished, without much patience and perseverance in the student.

All men, it is true, have not fufficient time and opportunities to acquire an accurate and extensive knowledge of nature; but those are inexcusable, who remain entire strangers to her ordinary operations, and particularly if they neglect to cultivate a proper acquaintance with the constitution of their own frame. If, indeed, we were fixed to the earth like the trees by their roots, or if from mere animal instinct we were stimulated to inquire into the causes of our physical life, we then should vegetate, or live like plants or irrational animals. But, in the character of creatures, who ought to choose and to reject agreeably to the dictates of reason, a more assiduous and minute study of nature, as well as of our own frame, is indispensable; because the human body cannot subsist, unless we fecond her intentions and co-operate with her beneficent efforts.

Difference of Opinions on Medical Subjects.

It is not unfrequently objected, that Medicine itself is an uncertain, fluctuating, and precarious art. One medical school, for instance, considers the mass of the fluids as the

primary cause of all diseases; another ascribes them to the irregular action of the folids, and particularly the nerves; fome again consider that as the cause of the disorder, which many are inclined to reprefent as the effect. Thus, different schools propagate different tenets relative to the origin of difeases; though ultimately, with respect to matters of fact, they must all necessarily agree. Nor is this diversity of opinions in the least degree detrimental to the practical department of Medicine; provided that we do not regulate the mode of treatment altogether by hypothetical notions. Of what confequence is it to the patient, whether his phyfician imagines the nerves to be fine tubes, filled with a fubtle fluid, or not? whether he believes that catarrhs arise from noxious particles floating in the air, or from catching cold ?-or whether he is prejudiced in favour of this or that particular theory of fevers?-It is a sufficient security to the patient, if his physician be thoroughly acquainted with the fyinptoins of the disease, and be able to distinguish them from those of any other malady. In this respect, the medical art is truly excellent, and without a rival; for the nature of diseases remains invariably the same. The accurate observations made by Hippocrates, two thousand years ago, on the progress and symptoms of diseases, recur to the medical practitioner of the present day, in a manner fufficiently regular and uniform .-And, in fact, how should it be otherwise; when nature always purfues the fame path,

whether in a healty or discassed state of the

body?

Here again it will be asked, whence does it happen that two physicians feldom agree in opinion, with regard to the case of the fame patient? This question may be briefly answered, by claiming the same right for the medical profession, which is assumed by theologians in contested points of divinity; by lawyers in arguing any part of their code, which is not perfectly plain; and by philofophers who maintain different opinions on the fame subject in metaphysics; for instance, that of space and time. But there are more forcible reasons which enable us, in some measure, to account for this diversity of opinions in Medicine. One of the physicians, perhaps, is in the habit of visiting fifty patients in a forenoon, fo that he has not fufficient time to investigate minutely the nature and origin of the disease; while another of less extensive practice is enabled to do more justice to his patients, by attending to their complaints with proper leifure and accuracy. One of them shall distinguish someof the leading symptoms, and without hesitation pronounce, that he has discovered the true feat of the malady; but as many difeafes of a different nature are attended with fimilar and common fymptoms, there is no fmall danger of confounding the one with the other. Another shall enter the patient's room with a pre-conceived opinion on the fubject of some prevailing epidemic, or with his head probably full of the case which occupied his

attention in the last visit. With these impediments, how difficult will it be to institute a cool and unbiaffed inquiry? If, again, both should happen to be called in at different stages of the disorder, each of them would prescribe a different method of cure, and the judgment of him who was last consulted, would in all probability be the most correct. Or lastly, a physician may be sent for, who, having commenced his studies about the middle of this century, has not (from want of time or inclination) fufficiently attended to the more recent discoveries of this inquisitive age; how can it then be expected, that he should agree in opinion with those, whose knowledge has been improved by the numberlefs new facts and observations lately made in physics, particularly in Chemistry?

Origin and Causes of Discase.

Man is subject to the same destructive agents from without, by which the lower animals are affected; but there is no doubt, that he is more easily and frequently exposed to diseases than these. First, The inferior creatures are unquestionably provided with a more active instinct, by which nature teaches them, from their very birth, to avoid every thing that may prove hurtful, and to choose whatever may have a salutary influence on their mode of living. Few traces of this beneficial instinct can be discovered in

the human race. Our own experience, or the instructions of others, which are likewise founded upon experience, must gradually teach us the wholesome or pernicious qualities of the objects of the material world.-Reason, indeed, that peculir faculty of man, indemnifies him, in a great measure, for the want of this instinct; it directs his choice in purfuing what is useful, and in avoiding what is injurious. Yet at the same time, the want of instinct in man, is the source of many fufferings in the earlier years of his life.-He is born without covering, to withstand the effects of climate; without arms, to defend himself in his helpless state, and without instinct, if we except that of sucking. He remains much longer incapable of providing for his felf-preservation, and stands in need of the affiftance of his parents for a much greater number of years, than any other animal with which we are acquainted. Although his parents, in general, acquit themfelves of this charge with much greater folicitude and tenderness than the lower animals, yet our imperfect instinct is productive of much mischief to children, from ignorance and ill directed tenderness in parents and nurses. Children are frequently furnished with articles of food and drefs which, at a more advanced age, nourish the feeds of difease and dissolution. Thus, many infants are indebted for their obstructions in the mesentery, and the confumptive habit attending them, to their uninformed and over anxious parents or friends, who commit daily errors with regard to the quantity and quality of the aliment, which in many inftances they so liberally administer to the objects of their care; even though it be of an indigestible nature.

In the fecond place, it is a fact univerfally admitted, that mankind, especially in large and populous towns, have much degenerated in bodily strength, energy of mind, and in their capacity of resisting the noxious agency of powers which affect them from without.

The progressive cultivation of the mind, together with the daily refinements of habits and manners, are ever accompanied with a proportionate increase of luxury. But as this change, from a robust to a more relaxed state of life, has produced no difference in the causes generating disease, to which we are even more subject than formerly, we must necessarily suffer by the concomitant effects. For though luxury has affisted us in preventing the temporary effects of external agents, fuch as cold, heat, rain, &c. and we can occasionally guard ourselves against their severity, we are, upon the next return of them, attacked with much greater violence, than if we had been more habituated to their influence. And this state of things has imperceptibly introduced the use of many articles, both of drefs and aliment, which in their consequences often prove detrimental to health. Hence we find, that in proportion as the refinements of luxury increase in a nation, the number and variety of diseases also

increase. On the contrary, the more uncivilized a people continue, and the more their habits and customs approximate to a state of nature, the less are they affected by the causes of disease.

In the third place, we observe among the human race a greater number of prevailing passions, and man is more violently, and, for the time of their duration, more obstinately governed by them, than any other living creature. These emotions variously affect the human body. But the most noxious and oppressive than any other of all the passions, are terror and grief: The former of which is fometimes fo violent as to threaten immediate destruction. Controlled by their powerful influence, and hurried away by the impulse of the moment, the mind is rendered incapable of judging, and of properly selecting the means of allaying those passions.-Hence the remedies, to which we have recourse during the prevalence of passion, and which then appear to us the most proper, frequently lay the foundation of innumerable disorders, both of body and mind.

A fourth source of diseases among mankind, are various specific contagions; and perhaps the greater number of these originate in the atmosphere which surrounds us. This is highly probable, at least with respect to marshy exhalations, and the effluvia of regions rendered unwholesome by different manufacturing processes. Another class of contagious miasmata consists of those which cannot be traced to any certain origin. In-

deed, we daily observe their migrations; we perceive them moving from one individual to another, without fixing any stationary refidence: Yet they have hitherto frustrated every attempt made towards their extirpation. Of this unfettled nature are, the finall pox, the measles, the hooping cough, the influenza, and many other epidemics. The first of them, namely the finall pox, has of late years been very fuccessfully treated; and it is well known that fome of the most ingenious practitioners in Italy and Germany are, at this moment, employed in a ferious attempt, wholly to extirpate this contagion from the Continent of Europe; an object which has formerly been accomplished in the cases of the plague and leprofy.*

To deprive this loathfome difease of its destructive power, another method, perhaps more plausible and less computiory, has been lately attempted in this country, and strongly recommended by Disageneral Pearson, Woodville, and other practitioners. I allude to the inoculation for the ever-yex. It is sincerely to be wished, that their humane efforts may be crowned with success: and if it

^{*} The means employed by our anceftors, in febduing the virulence of these malignant disorders, consisted chiefly in separating every infected person from the healthy, and preventing all intercourse between them. For this purpose, many thousand houses of reception were then established and supported at the public expense, in every country of Europe; the diseased were instantly and carefully removed to those houses, and not permitted to leave them till persectly cured. A measure somewhat similar to this has lately been proposed, and laid before the Plenipotentiaries of the Continental Powers assembled at Rastadt, by Prosessor, Dr Faust, and other German Physicians. This proposal, however, differs essentially from the former method of extirpating contagious disorders: as, according to the modern plan, we understand every individual, whether willing or not, must submit to be inoculated for the small-pox.

On the Doctrine of Temperaments.

Since it is established by numberless facts, that the temperaments, as well as the diseases, of whole nations, are in a great measure influenced by their ordinary articles of food, it will no longer be doubted, that the most important consequences result from our aliment, whether of food or drink.

As the doctrine of temperaments is in itself highly curious and interesting, I think this a proper place for introducing some practical remarks, tending to illustrate that subject, and presenting a concise view of it, chiefly derived from the learned annotations of the celebrated Professor Sommering of Mayence.

"The doctrine of temperaments," fays he, "in the general acceptation of that term, must be allowed to have greatly misled the ancient physicians, and particularly those who lived before the time of Galen. We are not, however, to infer from this, that

be true that persons inoculated for the cow-pox are firever exempt from the infection of the fmall-pox, and that this artificial translation of morbid matter from the brute to the human subject is not attended with danger, it is of little consequence whether the cow-pox originate from any cutaneous disease of the milker, or from the grease of horses. For my part, I am not very sanguine in my expectations, which have often been disappointed on similar occasions; and till I can persuade myself of the persect analogy subsisting between the two diseases, nay of their homogeneous nature, I shall patiently wait for a greater number of facts tending to confirm the truth of the hypothesis. This, however, in my opinion, can be decided only, when the small-pox should appear as the prevailing epidemic.

They erred not, by admitting the existence of temperaments; for that seems now to be fully established; but by too great a fondness for generalization; by limiting the number of them to four, and fixing their attention in this division simply on the nature and composition of the blood, instead of regarding the whole animal economy. Thus, for instance, they knew many parts of the human body scarcely by their names, and were little, if at all, acquainted with the great influence of the nerves; while our modern physicians pay an almost extravagant homage to these fashionable co-operators in diseases, and frequently forget, in their attention to their favourites, the more important, at least more obvious, parts of the sluids.

"There is a certain line observable in all the more perfect animals, by which nature is regulated in performing the functions of body and mind; in preserving or impairing the health, and in exerting all those energies of life, on which the happiness of the creature depends. This line is various in different individuals, and the variety cannot be completely explained on the principle of the ancients, by a difference in the qualities of the blood alone; though a human body of moderate fize contains not less than thirty pounds weight of that fluid. Other terms must therefore be substituted for their fanguine, choleric, phlegmatic, and melancholy temperaments; but before we attempt them, it

will be necessary to take a more extensive

view of the economy of man.
"The causes of the difference of temper. aments are various: First; a difference in the nervous system, with respect to the number of the nervous fibres, their strength, and sensibility. A large brain, coarse and strong nerves, and great general fensibility, have always been found to be the marks of a cholerie or cholcrico-fanguine disposition. Hence proceeds the quickness of perception and capacity of knowledge in persons of this class, accompanied with great acuteness and strength of judgment, from the multitude of their ideas of comparison. These qualities are, however, in some measure counterbalanced by a violent propenfity to anger, and impatience under flight fufferings of body or mind. Medicines ought, therefore, to be cautiously administered to them, and in small quantities only. A diminutive brain and very delicate nerves have generally been observed to be connected with dull fenses, and a phlegmatic languor-fometimes with a taint of melancholy. To affect the organs of fuch persons, the impression of external objects must be strong and permanent. Their judgments are often childish from the want of ideas, and hence they are feldom able to make great progress in science. They are, however, more sit to endure labour, and the injuries of climate; confequently their medicines should be strong, and administered in large quantities.

"Secondly: Difference of irritability is another cause of difference of temperament. When the sibres are excited by the slightest stimulus to quick and permanent contraction, we may justly infer the existence of a choleric disposition; while a phlegmatic temper displays itself by opposite symptoms; the muscles being slowly contracted, and excited with dissiculty by the most powerful stimulus.

"Thirdly: The fibres and membranes of a phlegmatic person are remarkably soft to the touch; those of a melancholic person hard and dry, with greater tone and facility of contraction.

" Fourthly: There appears to be fufficient reason for the opinion, that an electric principle is dispersed through the atmosphere, which is communicated to the body, in different degrees, by respiration; which supplies the sibres with their natural tone; gives a more lively motion to the vessels; and increases the serenity of the mind. This principle does not exist in the atmosphere in equal quantities in all countries, nor even in the fame country at different feafons or hours of the day. Thus, during the influence of the Sirocco in Sicily, all the fibres are oppressed by languor; but when the air becomes more ferene and elastic, the natural energy of body and mind returns. All men do not inspire this electric matter in equal quantities, and thus a remarkable difference of temperament is produced.

C 2

" Fifthly: To these causes must be added the different nature and quantity of the blood. Thus, when the blood is highlystimulant, the heart is excited to more violent action; an increased secretion of bile promotes the vermicular motion, and a fuperfluity of mucus disposes to catarrh, &c. From these considerations it is evident, that there are causes sufficiently powerful to produce, at a very early period of life, an unal-terable predisposition to a certain temperament. That a complete change is ever effected, from a choleric habit, for instance, to a phlegmatic, cannot be confiftently admitted, at least while the laws of nature remain unalterable. I will, however, admit that the temperaments, though not completely changed, may be modified; -that the vehemence of some, and the languor of others, may to a certain degree be leffened; but this must be done by remedies suited to the class of the causes productive of a partic-ular temperament. Of these the principal

"I. A different regimen. Thus animal food imparts the highest degree of strength to the organs, enlivens the senses, and often occasions a degree of serocity; as is evident in cannibals, in carnivorous animals in general, in butchers and their dogs, in hunters, particularly when aided by the frequent use of spices, wines, and stimulating medicines. Vegetable diet, on the contrary, diminishes the irritability and sensibility of the system;

in a word, renders it phlegmatic.—Some authors indeed have confidered potatoes as being the means of contributing to that end; but I am not inclined to fubscribe to this doctrine; fince I have had occasion to obferve the lively temperament of the common people in Ireland.—Yet attention to this is highly necessary in those, who have the charge of children; as by the use of animal food, additional energy may be given to the sibres, and when their irritability is toogreat, it may be diminished by an opposite regimen.

"2. Education, both physical and moral, is another cause of alteration in the temperament of man. Its power is almost unbounded, especially in the more early periods of life; and hence it often happens, that whole nations seem to possess one com-

mon temperament.

"3. Climate, in its most extensive sense, comprehending atmosphere and soil, is a third cause of alteration. The activity and acuteness of a choleric habit are seldom to be sound in a region of perpetual sog; as for instance, in Holland. They are the natural produce of a warm climate, and require a gentle elevation of surface, with a moderately moist soil, and a serene, equal atmosphere.

"4. I have often observed an astonishing degree of activity communicated to the whole system, by an ardent define of learning; so that the temperament seemed to receive new life from every accession of knowledge."

edge.

"5. The want of the necessaries of life, on the one hand, or possession of the means of luxury on the other, variously modify the disposition;—and the liveliness of the temperament is also observed to rise or fall, according to the degree of political freedom.

"6. Age, company, and professional dutics greatly affect the temperament. Hence we seldom find any one who, at 56 years of age, retains the activity of that choleric or fanguine habit which he possessed at 36.

Those who follow nature, and not a plausible hypothesis, will be sensible how dissicult it is to classify and six the characteristic marks of the different temperaments; and it is rather a matter of doubt, whether the following rude sketch will be more successful than the attempts of others.

"All the modifications of temperaments appear to be varieties of the fanguine and

phlegmatic.

"I. The fanguine is variable. It is marked by a lively complexion; the veffels are full of blood; and perfons of this habit are feldom able to bear great warmth; they are predifposed to inflammations, and posses a high degree of irritability and sensibility. All is voluptuous in this temperament. They are sickle in every thing they undertake; are affable, and soon become acquainted, but as soon forget their friends, and are sufficious of every body. Whatever requires industry they abhor, and hence make little progress in science, till they advance in age.

health and serenity of the sanguine, with all

the perseverance of the choleric.

"3. In the choleric, the body is foft and flexible, without being dry and meagre as in the melancholic; the skin has a teint of yellow; the hair is red; the eyes dark and moderately large, with a penetrating expression, and frequently a degree of wildness; the pulse full and quick; the muscular contractions in walking, speaking, &c. are rapid; the bile is copious and acrid, and hence the vermicular motion is active, and the body not liable to costiveness. Persons of this class are particularly fond of animal food. They possess great magnanimity, are sitted for laborious undertakings, and seem born to command.

"4. He whose temperament is hypochondriacal, is a burthen to himself and others. Persons of this class are subject to diseases of the liver, and hence have a sallow complexion. They are never content with their situation, and are a prey to envy and suf-

picion.

"5. The melancholic temperament is marked by a gloomy countenance, finall, hollow, blinking eyes, black hair, a rigid or tough fkin, dry and meagre fibres. The pulse is weak and languid, the bile black, the vermicular motion flow. The perceptions of perfons of this disposition are quick; they are fond of contemplation, and are flow in the execution of labour, which they patiently undertake. They bear with resolu-

tion the troubles of life; and, though not enfily provoked, are nevertheless vindictive.

"6. The Baotic or rustic temperament has many of the qualities of the sanguine, in common with many of those of the phlegmatic. The body is brawny, the muscles have but little irritability, the nerves are dull, the manners rude, and the powers of apprehension weak.

"7. The gentle temperament is a combination of the fanguine, choleric, and phlegmatic. Universal benevolence is the distinguishing character of this class. Their manners are soft and unrussed. They hate talkativeness; and if they apply to science, their progress is great, as they are persevering and

contemplative. Lastly,

"8. The phlegmatic class is marked by a foft, white skin, prominent eyes, a weak pulse, and languid gait. They speak slowly, are little hurt by the injuries of the weather, submit to oppression, and seem born to obey. From their little irritability, they are not easily provoked, and soon return to their natural state of indifference and apathy."

On Patent or Quack Medicines.

ALTHOUGH there is but one state of perfect health, yet the deviations from it, and the genera and species of diseases, are almost infinite. It will hence, without difficulty, be understood, that in the classes of medical remedies there must likewise be a great variety, and that some of them are even of opposite tendencies. Such are both the warm and the cold bath, considered as medical remedies. Though opposite to each other in their sensible effects, each of them manifests its medical virtue, yet only in such a state of the body as will admit of using it

with advantage.

It is evident from these premises, that an universal remedy, or one that possesses healing powers for the cure of all diseases, is in fact a nonentity, the existence of which is physically impossible, as the mere idea of it involves a direct contradiction. How, for instance, can it be conceived, that the fame remedy should be capable of restoring the tone of the fibres, when they are relaxed, and also have the power of relaxing them when they are too rigid; that it should coagulate the fluids when in a state of refolution, and again attenuate them when they are too viscid; that it should moderate the nerves in a state of preternatural sensibility, and likewise restore to them their proper degree of irritability, when they are in a contrary state.

Indeed, the belief in an universal remedy appears to lose ground every day, even among the vulgar, and has been long exploded in those classes of society, which are not influenced by prejudice, or tinetured with fanaticism. It is, however, sincerely to be regretted, that we are still inundated

with a flood of advertisments in almost every newspaper; that the lower and less enlightened classes of the community are still imposed upon by a set of privileged impostors, who frequently puzzle the intelligent reader to decide, whether the boldness or the industry with which they endeavour to establish the reputation of their respective poisons, be the most prominent feature in their character.*—It was justly observed by the sagacious and comprehensive Bacon, "that a reslecting physician is not directed

* To illustrate this proposition farther, I shall quote the sensible remarks of a late writer, Mr. James Parkinson, who express hindest, in his "Medical Admonitions," when treating on the subject

of Catarth, in the following pertinent words:

"Most of the Nostrums advertised as onegh drops, &c. are preparations of optum, similar to the paregoric clixir of the shops, but disguired and rendered more deleterious, by the addition of aromatic and heating gums. The injury which may be occasioned by the indiscriminate employment of such medicines, in this discuss, be very considerable; as is well known by every person possessing.

even the finallest share of medical knowledge.

"It would undoubtedly be rendering a great benefit to fociety, ? Some medical man were to convince the ignorant of the pernicious confequences of their reliance on advertised Nostrums: but, unfortunately, the fituation in which medical men frand is fuch, that their best-intentioned and most disinterested exertions for this purpose would not only be but little regarded, but frequently would be even imputed to base and invidious motives. Those to whom they have to address their admonitions are unhappily those on whom reason has least influence. "Prithee, Doctor," said an old acquaintance to a celebrated empiric, who was standing at his door, "how is it that you, whose origin I so well know, should have been able to obtain more patients than almost all the regular-bred physicians?"-"Pray," fays the Quack, "how many perfons may have paffed us whilst you put your question?"—"About twenty."—"And, pray, how many of those do you suppose possessed a con petent share of common fenfe?"-" Perhaps one out of twenty."- Just fo," fays the Doctor; "and that one applies to the regular physician, whilst I and my brethren pick up the other nineteen."-P. 327 and 328.

by the opinion which the multitude entertain of a favourite remedy; but that he must be guided by a sound judgment; and consequently he is led to make very important distinctions between those things, which only by their name pass for medical remedies, and others which in reality possess healing powers."

I am induced to avail myfelf of this quotation, as it indirectly censures the conduct of certain medical practitioners, who do not scruple to recommend what are vulgarly called Patent and other Quack medicines, the composition of which is carefully concealed from the public. Having acquired their ill-merited reputation by mere chance, and being supported by the most refined artifices, in order to delude the unwary, we are unable to come at the evidence of perhaps nine-tenths of those who have experienced their fatal effects, and who are now no longer in a fituation to complain.

The transition from Panaceas, or universal remedies, to Noferums or Specifics, such, for instance, as pretend to cure the same disease in every patient, is easy and natural. With the latter also, impositions of a dangerous tendency are often practised. It will probably be asked here, how far they are practically admissible, and in what cases they are wholly unavailing. It is not very disticult to answer this question. In those diseases, which in every instance depend upon the same cause, as in agues, the small-pox, measles, and many other contagious distempers, the possibility of

D

specifics, in a limited sense, may be rationally, though hypothetically, admitted. But in other maladies, the causes of which depend upon a variety of concurrent circumstances, and the cure of which, in different individuals, frequently requires very opposite remedies, as in the Dropfy, the various species of Colic, the almost infinite variety of Consumptions, &c. &c. a specific remedy is an impudent burlefque upon the common sense of mankind. Those who are but imperfectly acquainted with the various causes from which the same diforder originates in different individuals, can never entertain fuch a vulgar and dangerous notion. They will easily perceive, how much depends upon afcertaining with precision the seat and cause of the affection, before any medicine can be prescribed with advantage or fafety:—even life and death, I am concerned to fay, are too often decided by the first steps of him, who offers or intrudes his advice upon a fuffering friend.

The following inflances will shew the danger attending the precipitate application of the same medicine in similar disorders.—A person violently troubled with the colic took a glass of juniper spirits, commonly called Hollands, from which he received almost instantaneous relief, as the affection proceeded from flatulency. Another person, who found himself attacked with similar pains, was induced by the example of his friend to try the same expedient; he took it without hesitation, and died in a few hours after.—No wonder that the consequences here were fatal.

as the colic in the latter case was owing to an inflammation in the intestines.—A third person was afflicted with a colic, arising from poisonous mushrooms, which he had inadvertently fwallowed; the immediate administration of an emetic, and after it, some diluted vegetable acid, restored him to health. A fourth person had an attack of this malady from an encysted bernia or inward rupture. The emetic, which relieved the former patient, necessarily proved fatal to the latter; for it burst the bag of inclosed matter, poured the contents within the cavities of the abdomen, and thus speedily terminated his existence. Again, another had by mistake made use of arsenic, which occasioned violent pains, not unlike those of a common colic. A large quantity of fweet oil taken internally was the means of his prefervation; whereas the remedies employed in the other cases would have been totally ineffectual. Here I willingly close a narrative, the recital of which cannot but excite the most painful fensations. lengthen the illustration would lead me too far beyond my prescribed limits: for cases of this nature happen so frequently, that it would be easy to extend the account of them, by a long catalogue of interesting but fatal accidents.

What is more natural than to place confidence in a remedy, which we have known to afford relief to others in the fame kind of affection? The patient anxiously inquires after a person who has been afflicted with the same malady. He is eager to learn the remedy

that has been used with success. His friend or neighbour imparts to him the wished-for intelligence. He is determined to give it a fair trial, and takes it with confidence. From what has been stated, it will not be difficult to conceive, that if his case does not exactly correspond with that of his friend, any chance remedy may be extremely dangerous, and even satal.

The physician is obliged to employ all his fagacity, supported by his own experience, as well as by that of his predecessors; and, nevertheless, is often under the temporary necessity of discovering from the progress of the disease, what he could not derive from the minutest researches. How then can it be expected, that a novice in the art of healing should be more successful, when the whole of his method of cure is either the impulse of the moment, or the effect of his own credulity? It may be therefore truly said, that life and death are frequently intrusted to chance.*

From what has been premifed, it may be confidently afferted, that a nostrum or an universal remedy is as great a desideratum as

^{*} The late Dr. HUXHAM, a physician of great celebrity, in speaking of Afilepiades, the Roman empiric, says: "This man from a declaimer turned physician, and fet himself up to oppose all the physicians of his time; and the novelty of the thing bore him out, as it frequently doth the Quacks of the present time; and ever will, websty the majority of the world are fools."

In another place, Dr. Huxham thus curiously contrasts the too timid practice of some regular physicians, with the hazardous treatment, which is the leading feature of Quacks: "The timid, low, inspired practice of some, is almost as dangerous as the bold, unwarranted empiricism of others; time and opportunity, never to be regained, are often lost by the former; whilst the latter, by a bold push, send you off the stage in a moment."

the philosopher's stone. The absurd idea of an universal medicine can only obtain credit with the weak, the credulous, or the ignorant.

One of the most unfortunate circumstances in the history of such medicines, is the infinuating and dangerous method, by which they are puffed into notice. And as we hear little of the baneful effects which they daily must produce, by being promiscuously applied, people attend only to the extraordinary instances, perhaps not one in sifty, where they have afforded a temporary or apparent relief. It is well known, that the more powerful a remedy is, the more permanent and dangerous must be its effects on the constitution; especially if it be introduced like many Patent-Medicines, by an almost indefinite increase of the doses.

There is another confideration, not apt to firike those who are unacquainted with the laws of animal economy.—When we intend to bring about any remarkable change in the fystem of an organized body, we are obliged to employ such means as may contribute to produce that change, without affecting too violently the living powers; or without extending their action to an improper length. Indeed, the patient may be gradually habitue ated to almost any stimulus, but at the expense of palsied organs, and a broken constitution.*

"I was once healthy; I wished to be better; I took medicine, and died."

^{*} An Italian Count, uncommonly fond of fivallowing medicines, found at length that he could take no more. Previous to his death he ordered the following infeription to be placed on his tomb:

Such are the melancholy effects of imposture and credulity! Were it possible to collect all the cases of sacrifices to this mysterious infatuation, it is probable that their number would exceed the enormous havoc made by gun-

powder or the fword.

A popular writer, Dr. Buchan, makes the following just remark on the subject in question: "As matters stand at present," says he, "it is easier to cheat a man out of his life, than of a shilling, and almost impossible either to detect or punish the offender. Notwithstanding this, people still shut their eyes, and take every thing upon trust, that is administered by any pretender to Medicine, without daring to ask him a reason for any part of his conduct. Implicit faith, every where else the object of ridicule, is still sacred here."

Analysis of Fashionable Complaints.

If these abuses of medicine be of consequence, how much more so are certain manners, habits, and customs, which the united efforts of the Faculty will never effectually remove or suppress, unless affisted by the semale guardians of helpless infancy. That I may not be misunderstood with respect to the real intention of this address to the fair sex, I beg leave previously to observe, that the following remarks apply chiefly to certain classes of the community, among whom a due degree of attention is but rarely paid to the skin of their offspring.

The greater number of our fathionable complaints and affections are nearly related

to each other. The gout, formerly a regular but rare disease, which attacked only the external parts of persons advanced in years, has now become a constitutional indisposition, a juvenile complaint, torturing the patient in a thousand different forms. The famous Podagra and Chiragra of our ancestors are now nearly obsolete, and instead of the gout in the fect or hands, we hear every day of the nervous gout, the gout in the head, and even the fatal gout in the stomach. No rank, no age, no mode of life feems to be exempt from this fashionable enemy .- The next and still more general malady of the times, is an extreme fenfibility to every change of the atmosphere; or rather, a constantly sensible relation to its influence. We are not only more subject to be affected with every current of air, every change of heat and cold, but the feelings of some are so exquifitely delicate, that in a close apartment, nay in bed, they can determine with accuracy the state of the weather, as well as the direction of the wind. By confulting their bodily fensations, these living barometers announce more correctly than the artificial ones, not only the present, but even the future changes of the weather. I could never have believed, that this additional fense, which is only of modern origin, could be fo much improved, had I not frequently witnessed the fensations of certain patients, when a cloud is floating over their heads :- a talent fo peculiar to our age, that it would undoubtedly excite furprise, but no envy, in our less resined forefathers. In a climate, where the weather

changes every day, and almost every hour, it may be easily imagined, how dependent, frail, and transitory, must be the health of the wretched possessor of this new sense; and that beings so organized cannot warrant, for a single hour, their state of health, their good-humour, or their physical existence. Is it not then very probable, that many strange and inconsistent events of our days may have their secret foundation in this dependence on the weather?—In judging of man and his actions, we ought first to observe the state of the barometer; as our more superstitious ancestors made the celestial constellations the criterion in their prognostics.

Not less characteristic of the present generation, but more painful, are the fashionable nervous and hypochondriacal diseases. These are formidable, insidious tormentors, which not only destroy our physical well-being, but also envenom our tranquillity and contentment, and cloud our fairest prospects of happiness. Without depriving us of life, they render it an insupportable burthen; without inducing death, they make him a welcome

visitor.

It is unnecessary to detail the diversified shapes, in which these maladies present themselves. Let it suffice to observe, that however intimately the mind appears to be connected with these phenomena, we can nevertheless account for them from physical causes. They have rapidly increased with the propagation of the gout, and experience shews, that they frequently alternate with it, in the same in-

dividual patient. It is highly probable, therefore, that they are of a fimilar nature with the gout; and that they originate from the fame fource, which is peculiar to our age. Closely connected with the gout, and likewise with the hypochondrias, how frequently do we observe the hamorrhoids, formerly a discase of the aged, now the companion of youth,

and almost a general complaint.

The last class of our fashionable diseases includes all those affections of the skin, which are known by the name of cruptions, discolorations, efforeseences, scorbutic taints, &c. Of late, these have alarmingly increased, and appear daily to spread every where, like noxious weeds. Even in the higher ranks, where neither a poor diet, nor want of attention to cleanliness, can be assigned as causes, we frequently observe persons, whose skin announces bad health, and on whom medicine can have no effect. Physicians of different countries complain of new and unheard-of cutaneous diforders, of an extremely malignant tendency; and if the spreading of them be not checked in time, Europe will perhaps once more be vifited with that malignant and filthy difeafe, the Leprofy.

It is however not fusicient to give a bare catalogue of these singular affections. I shall, therefore, attempt to trace them to their source; to shew that they can be easily prevented; and to point out the most likely means by which so desirable an event may be accomplished.—It is to you, guardians of suture, and I hope hardier races, that I now ap-

peal—it is your aid I folicit in fo important a measure of national and domestic policy.

On the Nature and Tunctions of the Skin.

Much as we hear and speak of bathing, and of the great attention at present paid to cleanlines, I am bold to assire, that the greater number, if not the whole of our fashionable complaints, originate from the want of care and proper management of the skin. Through unpardonable neglect in the earlier part of life, especially at the age of adolescence, the surface of the body is so unnaturally enervated by constant relaxation, that it oppresses, and, as it were, consines our mental and bodily faculties; promotes the general disposition towards the complaints above alluded to; and, if not counteracted in time, must produce consequences still more alarming and deplorable.

We often hear people complain, that their skin is uneasy; a complaint, which I fear is but too prevalent among those, who give themselves little trouble to inquire into its origin.—But how is it possible, I hear many persons ask, that the skin, which is a mere covering of the body, to shelter it from rain and sunshine, can have such insluence over the whole frame? I shall venture to explain this problem, and hope to impress such as are inclined to be sceptical, with more respect for that part of

the human body.

The skin unites in itself three very essential functions. It is the organ of the most exten-

five and useful sense, that of touch; it is the channel of perspiration, the principal means which Nature employs to purify our fluids; and through the most admirable organization, is enabled to absorb certain falutary parts of the furrounding atmosphere, and to guard us against the influence of others of an injurious tendency. For this purpose, innumerable nerves and vessels are dispersed throughout the skin, which are in the continual act of feeling, and at the same time of secreting and volatilizing noxious particles, and abforbing those containing vital principles. It has been proved by accurate calculations, that the most healthy individual daily and infenfibly perspires upwards of three pounds weight of fuperfluous and hurtful humours. therefore be confidently afferted, that no part of the body is provided with so many and important organs, by which it is connected with almost every operation performed in an-imal life, as the skin. It is this, which places us in the most immediate connexion with the furrounding atmosphere, which through that channel particularly affects us, and exerts its influence on our health :- we further feel, directly through the skin, the qualities of the air, heat, cold, preflure, rarefaction, &c.: and hence we experience, at least in their influence, other much more fubtle and lefs known qualities, of which I shall only mention the electric and magnetic fluids. From the spiritual and highly penetrating nature of these sluids, we may easily conjecture, how considerable a share they must have in the principle of vitality, and of what important use the

organ is, through which they affect us.

Important as the skin is to external life, it is no less fo to the internal economy of the body, where it appears to be peculiarly de-figned to preferve the great equilibrium of the different Tystems, by which the human frame is supported in its vital, animal, and fexual functions.—If any stagnation, accumulation, or irregularity arise in the sluids, the skin is the great and ever-ready conductor, through which the fuperfluous particles are feparated, the noxious volatilized, and the fluids, stagnating in their course, set at liberty; a canal being at the fame time opened for the removal of those humours which, if they should get access to the vital parts, such as the heart and the brain, would cause incritable destruction. By the proper exercise of this organ, many difeafes may be suppressed in their early stages; and those which have already taken place may be most effectually removed. No disease whatever can be removed without the co-operation of the skin. The nature and conflitution of this organ most certainly determine either our hope or apprehension for the safety of the patient. In the most dangerous inslammatory fevers, when the prospect of recovery is very faint, a beneficial change of the fkin is the only effort, by which Nature, almost overcome, relieves herfelf, and ejects the poison in a surprising manner, frequently in the course of one night. The greatest art of a physici in, indeed, consists in the proper management of this extensive organ, and in regulating its activity, where occasion requires. To mention only one circumstance; it is well known to those who have experienced the beneficial effects of a simple blister, that its stimulus, like a charm, has frequently relieved the most excruciating

pains and spasms in the internal parts.

Cleanliness, flexibility and activity of the skin are, according to the observations premised, the principal requisites to the health of individuals, as well as of whole nations. But instead of contributing to its improvement, we generally pay very little attention to it, except to the skin of the face and hands, which are too often made the fallacious index of health. I am convinced, however, that most of the patients and valetudinarians, who take fo much pains to refresh and fortify the internul parts of their body, by invigorating potations, rarely, if ever, pay any regard to their external furface; -an object of equal importance, and perhaps standing in much greater need of corroborants than the former. Hence it happens, that the skin of convalescents is observed to be particularly relaxed and obstructed; that they are liable to continual colds, upon the least change of temperature; and that every day of their recovery renders them more subject to relapses.

In this country, the children of people in the middling and lower ranks are perhaps better managed, than in most of the countries upon the Continent; because frequent and daily bathing is, to my certain knowledge, no where so generally practised as in England. As foon, however, as children attain a certain age, this practice is again as generally neglected: after the tenth or twelfth year of age, the furface of the body is very little attended to. Thus a foundation is laid for numberless evils, and particularly for that scorbutic taint in the human system, which now almost univerfally prevails, and which is more or lefs connected with other and more fashionable complaints.—As we advance further in years, this disposition of the skin increases still more, particularly from the mode of life purfued in the higher ranks. We then begin to accuftom ourselves to sedentary habits, to think, and to partake of the pleasures of life. The lady, the man of fortune, and the ill-fated man of letters, all of them require more active exercife, than they actually take, which alone can promote a free perspiration, and enliven the surface of the body; but, by their indolent habits, the whole machine stagnates, and the skin becomes contracted and debilitated.

The hufbandman, indeed, labours diligently; and though, by the fweat of his brow, his skin preserves more life and activity, it is neither kept sufficiently clean, nor prevented from being obstructed by perspirable matter. The artist and manufacturer carry on their pursuits in a sedentary manner, and in a consined, impure air; the latter, in the duties of his occupation, generally employs unwhole-some articles, so that at length he loses the use of this organ entirely, in some parts of the body. The voluptuary and the glutton do not suffer less than the former, as they impair the

energy of the Ikin by excesses of every kind, and take no precautions to preserve its elastic texture.—Our usual articles of dress, slannel excepted, are not calculated to promote a free perspiration;—our coal-sires, and still more the large potations of warm liquors, contribute greatly to relax the skin. If we add to this list of predisposing causes, our inconstant climate, which at one hour of the day braces, and at another relaxes the surface of the body, which alternately heats and cools it, and consequently disturbs its uniform action; it will be easily understood, that the skin must for these reasons be almost generally vitiated, and that it really is a leading source of many of

our fashionable indispositions.

When the fensation of the surface is impaired; when the myriads of orifices, that are defigned for the continual purification and renovation of our fluids, are obstructed, if not closed; when the fubtle nervous texture is nearly deprived of its energy, fo that it becomes an impenetrable coat of mail, is there any reason to wonder, that we are so often harassed by a fenfe of constraint and anxiety, and that this uneafiness, in many cases, terminates in a desponding gloom, and at length in complete melancholy?-Ask the hypochondriac, whether a certain degree of cold, paleness, and a spasmodic sensation in the skin, do not always precede his most violent fits of mental debility; and whether his feelings are not most comfortable, when the surface of his body is vigorous, warm, and perspires freely? In short, the degrees of insensible per-

spiration are to him the safest barometer of his state of mind. If our skin be disorganized, the free inlets and outlets of the electric, magnetic, and other matters, which affect us at the change of the weather, are inactive. Thus the origin of extreme sensibility towards the various atmospheric revolutions, is no longer a mystery. For, in a healthy surface of the body, no inconvenience will follow from fuch changes.—If we further advert to those acrimonious fluids which, in an imperfect state of perspiration, are retained in our body, and which fettle upon the most fensible nerves and membranes,—we shall better apprehend, how cramps or spasms, the torturing pains of the Gout and Rheumatifin, and the great variety of cutaneous discases, have of late become fo obstinate and general.

The equilibrium of the Inids, and the circulation of the blood, are also determined in no small degree by the skin; so that if these sluids become thick and languid, the whole momentum of the blood is repelled towards the interior parts. Thus a continual plethora, or fulness of the blood, is occasioned; the head and breast are greatly oppressed; and the external parts, especially the lower ex-

tremities, feel chilly and lifelefs.

In warm climates, in Italy for instance, the hæmorrhoids, a very distressing complaint, are but rarely met with, notwithstanding the luxurious and sensual mode of life of the inhabitants; because perspiration is always free and unchecked: while among us persons are found, who devote the whole of

their attention to the cure of that troublesome disorder.

May we not infer, from what I have thus advanced, that the use of baths is too much neglected, and ought to be univerfally introduced? It is not sufficient, for the great purposes here alluded to, that a few of the more wealthy families repair every feafon to watering-places, or that they even make use of other modes of bathing, either for their health or amusement. A very different method must be pursued, if we seriously wish to restore the vigour of a degenerated race. I mean here to inculcate the indispensable neceflity for domestic baths, so well known among the ancients, and fo univerfally established all over Europe, a few centuries ago, and which were eminently calculated to check the further progress of the leprosy; --- a disease which, though flower in its effects, is not less diffresting than the plague itself.

Much has been faid and written upon the various methods, and the univerfal medicines, proposed in different ages, by different adventurers, professedly to diminish the inherent disposition to disease, and to give a new and renovating principle to the human frame. At one time they expected to find it in the philosophic and astralian salts, at another in Magnetism and Electricity;—some fanatics pretended to have discovered it in the light of the moon, others in celestial beds;—but, if I may venture to deliver my opinion, we may search for it most safely and conveniently

in every clear fountain—in the bosom of ever

young, ever animating nature.

Bathing may be also considered as an excellent specific for alleviating both mental and bodily fufferings. It is not merely a cleanfer of the skin, enlivening and rendering it more fit for performing its offices; but it also refreshes the mind, and spreads over the whole fystem a sensation of ease, activity, and pleasantness. It further removes stagnation in the larger as well as in the capillary veffels; it gives an uniform free circulation to the blood, and preserves that wonderful harmony in our interior organs, on the disposition of which our health and comfort so much depend. A person fatigued, or distressed in body and mind, will derive more refreshment from the luxury of a lukewarm bath, and may drown his difquietude in it more effectually, than by indulging in copious libations to Bacchus. The bath may be equally recommended as an admirable retiring place, to evade, for a time, the influence of the atmosphere; and persons that have the misfortune to be too susceptible of external impressions, would find no small benefit, were they to repair in thick and fultry weather to the bath, where they breathe in an element less loaded with noxious particles.

The wish to enjoy perpetual youth, is one of the most predominant and pardonable. Though it cannot be rationally afferted, that bathing will confer continual youth, yet I will hazard an opinion, that it has a very uncommon and superior tendency to prolong

that happy state; it preserves all the solid parts soft and pliable, and renders the joints of the body slexible. Hence it powerfully counteracts, what I presume to call an insidious disease, viz. age, which operates by gradually exhausting the humours, and depriving the constituent parts of the human frame of their elasticity. It is no less certain, that bathing is one of the most efficacious means of preserving beauty; and that those nations, among which bathing is a prevailing practice, are usually the most distinguished for elegance

of form and beauty of complexion.

A moderate defire to improve and beautify the furface of the body, is far from being a frivolous pursuit. It excites as much interest, and is productive of as beneficial confequences, as the exertions of many a pseudo-philos-opher, who devotes the toil of years, to arrange his notions in a certain systematic form, and who yet is not fortunate enough to attain the great object of his wish. I have had frequent opportunities to observe, that the defire of beauty, when not inordinate, may prove the fource of many virtuous and laudable pursuits, and that it may be greatly instrumental to the preservation of health. I am also persuaded, that this desire is often purfued by methods not the most proper, and that from not having a just knowledge of beauty, we make many valuable facrifices, not only of things relating to health, but fornetimes of life itself. Instances are not uncommon, of young persons attempting to bleach their skins, and beautify their persons,

by avoiding a free air, using a mild and weak-ening diet, long fasting, long sleeping, warming their beds, &c. &c.; but, alas! the event does not answer their expectation,—they lose both health and bloom!—Eating chalk, drinking vinegar, wearing camphorated charms, and fimilar destructive means have been reforted to, by other more daring adventurers, but with no better fuccess. Those I have last enumerated, may be called the minor cosmetics: others of a more formidable nature, I almost hesitate to mention, as they are unquestionably the most deleterious substances we are acquainted with. Mercury and lead, manufactured in various forms, are unhappily too common ingredients in many of our modern cosmetics, whether they consist of lotions, creams, powders, paints or ointments. That these substances can be communicated to the circulating fluids, through the skin as well as by the stomach, requires, I should suppose, no further proof, after the dostrines already advanced on this fubject. Lead, in particular, if once introduced into the fystem, though in the finallest proportions, cannot be removed by art, and never fails to produce the most deplorable effects; fuch as palfy, contraction and convulsion of the limbs, total lameness, weakness, and the most excruciating colic pains. Besides these more obvious effects, the frequent external use of lead and mercury, as cofmetics, occasions cramps in every part of the body, faintings, nervous weakness, catarrhs, tubercles in the lungs and intestines, which occur together or feparately, according

to the different circumstances, till at length a confumption, either pulmonary or hectic,

closes the dreadful scene.

Beauty of the skin, the subject under consideration at present, is but another term for a found and healthy skin;—a pure mirror of the harmony of the internal parts with their surface, or, if I may be allowed the expression,

" it is visible health."

There fublists so intimate a relation between our interior and exterior veffels, that almost every error or irregularity in the organs within, shows itself first of all on the surface without, and particularly on the face.-How often are we struck at the countenance of a perfon, who thinks himself in perfect health, but whose illness, the result of some morbid cause concealed in the body, justifies in a few days the ferious apprehensions we entertained at our last interview. Nature has wifely ordained, that the first appearance of internal irregularities is indicated by the countenance; but to what use do we generally apply this index?—We resuse to avail ourselves of her beneficent intimation; and the continued use of pernicious fubstances, instead of promoting the object we have in view, ultimately tarnishes and impairs that beauty, which we meant to adorn and preserve. We imagine it in our power to improve the skin, without attending to the purity of the fluids, although it is indebted to them for its very existence; and yet should finile at a person, who attempted to cleanfe an impure tongue, by constantly teraping it, when a difordered from ich was the real cause of that impurity.

From the tenor of the preceding politions, I hope for indulgence, when I venture to pronounce every cofmetic, whose composition is kept a fecret from the public, false and fraudulent ware. The three great and really effectual Substitutes for Cosmetics,* which I would recommend, are the following: First: due attention to infensible perspiration;—an important process, by which nature, if duly assisted, will not fail to expel all acrimonious or uscless particles. By this, too, the surface of the body will be kept in a constant atmofphere of foftening exhalations,—a species of volatile vapor-bath, and the most efficacious means of preserving it soft and pliant, and of animating it with the colour of life. The next circumstance to be attended to, is the purity of the fluids; this depends equally on a free perspiration, and on a vigorous state of digestion. The third requisite to a fair, healthful complexion, is an uniform distribution of the fluids; or in other words, a free and un-

^{*} To fuch readers, whether male or female, as are determined to make use of cosmetics, instead of attending to the more effectual means to preserve the bloom of the skin, it may be of service to point out one or two external applications, in order to prevent them from reforting to the dangerous and destructive contrivances of Quacks.-According to Dr. WITHERING, a physician of great eminence at Birmingham, an infusion of horse-radish in milk makes one of the fasest and best cosmetics. Another preparation for clearing the skin of pimples and recent eruptions, if affifted by gentle aperient medicines, is the fresh expressed juice of house-leek, mixed with an equal quantity of fweet milk or cream.-Yet all contrivances whatever, to anfwer this purpose, are absurd and nugatory, if the inward state of the body be neglected, or if they be looked upon as specifics of themselves. Such things do not exist in nature; and we might as well try to bleach the face of a Negro, as to remove any fcorbutic or other eruptions from the face, without bestowing proper attention on the whole state of the body, and particularly the fluids, from which these irregularities derive their origin,

restrained circulation of the blood; as the very purest fluids, when profusely propelled to the face, are productive of disagreeable consequences, such as unnatural redness, sushings, tumid appearances, &c. of which ladies of a sed-

entary life are so apt to complain.

To these three general observations, I think, it may be necessary to subjoin a few particular injunctions, relative to the improvement of the skin, as connected with a state of good health.—Carefully avoid all immoderate and violent dancing, as the fudden alternations of heat and cold, not only impair the general state of the skin, but are likewise of the greatest detriment to beauty.-Abstain from the too frequent and too copious use of heating liquors of every kind, particularly punch and strong wines. There is scarcely any thing which is, in my opinion, more destructive of the bloom of . youth and manhood, than this liquid fire, which fills the blood with inflammable particles, propels them towards the face, parches the fkin, renders it spotted, and lays the foundation of that incurable difeafe, which is fometimes figuratively called copper in the face. Neither fugar, nor any additional ingredient to gratify the palate, can deprive these liquors of their noxious qualities, fo that even the most agreeable of these seductive potions is attended with confiderable danger.

Avoid, likewise, every excess in hot drinks, as cossee, chocolate, and tea, particularly the last, in which the people of this country are given to indulge, more than in any other beverage. I scarcely dare venture to impeach

this favourite folace of our morning and evening hours; but with all due deference to the comforts of the domestic circle, I consider it as my duty to denounce the too liberal use of this liquor, as not a little prejudicial to the fairness and purity of the skin. Tea taken hot, and in immoderate quantities, not only has a tendency to weaken the organs of digeftion, but causes fluctuations and congestions in the humours of the face, and frequently brings on a degree of debilitating perspiration. Let us conceive the flomach inundated with a portion of warm water, just at the time of digestion; its concoctive powers are literally drowned, at the very instant when their assistance is most required; and, instead of a pure balfamic chyle, or alimentary fluid, it prepares crude, and acrimonious humours, which can only generate an unhealthy mass of blood. Here, I cannot impress upon the attentive reader, in terms fufficiently strong, the following truth: that a healthy stomach only can produce bealthy and uncontaminated fluids; and that two thirds of what we call acrimony, or sharpness of humours in the fystem, proceed from a languid stomach, and irregular digestion.-If therefore the tea be made too weak, it will operate merely as warm water, and like it will greatly relax the coat and membranes of the flomach; -if made too ftrong, it will give an unnatural heat to the body, prove a dangerous stimulus to the nerves, occasion palpitations of the heart, universal trembling, cramps, and a number of other complaints, which it is needless to enumerate. That these

effects do not take place, during the first months or years of indulging ourselves in the intemperate use of hot and strong tea, is no argument to controvert this position; they will, either sooner or later, unavoidably sollow.

I shall but slightly touch here, on another subject, scarcely of less importance than the former; namely, the various articles prepared by the pastry-cook and confectioner. These dainties would be less objectionable, if any method could be devised of baking them without the pernicious ingredients of yeast and fat, substances which load the stomach with a glutinous slime and rancid matter, which obstruct the glands of the abdomen, particularly those of the mesentery, and which have a strong ten-lency to produce the cutaneous diseases before mentioned.

On the Physical Education of Children.

The physical education * of infants unquestionably forms an object of the first importance. The great disproportion sublishing between healthy and diseased children, together with the deplorable mortality which occurs among the latter, too plainly evince, that their bodily welfare is not sufficiently attended to.

There is little room to doubt, that by a more rational mode of nurture, during the

To fome readers it may be necessary to explain, that by physical decation is meant the bodily treatment of children: the term physical being applied in opposition to moral.

first years of infancy, many subsequent diseases might either be wholly prevented, or at least greatly mitigated. Nothing perhaps would contribute more to meliorate education in general, than, what has been long and much wanted, a serious and minute attention of the Faculty to this particular branch of medical study: which at present, I am concerned to

fay, is almost totally neglected.

The few books extant on this subject are neither written on scientistic principles, nor calculated, by their manner and style, to aftord plain and popular instruction. It is not enough for professional men to plan systems of education in their study-rooms;—let them also demonstrate in practice, that they are familiarly acquainted with the true method of educating children;—a method which, in my opinion, implies somewhat more than merely prescribing and administering medicines.

So long as the nursing of children remains exclusively in the hands of common midwives and nurses, it is rather a matter of surprise, that so many infants should survive the age of childhood.—We ought therefore, above all things, to inquire into the monstrous prejudices prevailing in this essential part of domestic management, as the sirft step towards their extirpation.

How great would be my fatisfaction, if, by the following ftrictures, I should be able to prevail upon some intelligent mothers, who possess fusicient fortitude, to throw off the bondage of old customs, or modern fashions, and to return to the path of simple nature!—In a system of practical education, it is a judicious precept, which cannot be too much inculcated, to omit rather than to undertake, or be too officious, in the physical treatment of infants.

From the difficulty of discovering the true cause and seat of the complaints of children, especially if accompanied with any particular fymptoms in the excretory vessels, it is very usual to administer a gentle laxative or emetic, upon the flightest occasion.-It would lead me too far to examine, in detail, the many bad confequences refulting from fo abfurd and detrimental a practice. I cannot, however, forbear from remarking, that by dealing constantly in aperient medicines (a strange infatuation among the vulgar!) the future diseases of the child assume a particular character of the gastric kind—the juice of the stomach, which ferves to concoct our food, being vitiated. As the operation of the laxatives is in a manner mechanical, by impelling the fluids, and particularly those of the mucous kind, towards the stomach and bowels, and causing them to accumulate in a greater degree than usual, it will be easily understood, that by the frequent repetition of this stimulus, the gastric juice will be rendered unfit to effect the proper folution of food in the stomach. For the same reason, persons subject to frequent costiveness foon begin to complain of indigestion, when they once habituate themselves to take An-DERSON'S or any other apericut pills: for by them the stomach is converted, as it were, into a field of battle, where all the irregularities, that take place in the fystem, are left to fight their way; where the limits of disease and health, nay the alternative of life and death, are to be finally determined. That this however is not the most proper place for fuch a contest, requires no demonstration. The stomach is appointed by nature for very different purposes; it is the only organ of nourishment and digestion; the source of reftoration and health. But how can it effectually answer this end, if it serves, at the same time, as the conftant laboratory of diseases? As it is always in a state of impurity, it cannot act with uniform energy and a fufficient degree of elasticity, to prevent frequent irregularities in digestion; -hence arise bad humours, hypochondriac affections, and nervous debility; all of which, I have reason to fear, are, more or less, consequences of tampering with medicines, especially in the period of childhood. I am further induced to think, though it may to fome appear rather a bold idea, that more children are destroyed by the absurd practice of loading their tender stomachs with every fort of trash, and afterwards relieving them by repeated doses of physic, than by any natural process. This likewise accounts for the great number of children who die in towns, at an early age, before they become inured to fuch fevere attacks made on their digestive organs.

In order to check, and, if possible, to prevent, this general tendency to discases; to meliorate the constitution of children, by producing a regular circulation of the sluids;

and to direct the exuding morbid matter more univerfally and uniformly through the pores of the Ikin, a more effectual remedy cannot be fuggested, than that of frequent bathing, and a very limited use of aperient medicines.

These observations are not conjectural, but founded on experience, and it gives me pleasure to add, that they are confirmed by many physicians of eminent abilities, and extensive

practice.

Frequent bathing in infancy is a powerful mean of counteracting and fuppressing the disposition to stomachic and bilious complaints, which, in our days, are uncommonly prevalent among children and adults, and which are frequently accompanied with diversified nervous symptoms. By the efforts of nature, to throw off malignant humours by the surface of the body, in consequence of a proper use of the bath, many infantile discases may be safely prevented, catarrhs suppressed, or greatly mitigated, teething rendered easy, and the whole physical condition of the child considerably improved.

It becomes here a question, which is the most proper degree of heat in using the bath for children.—I shall venture to pronounce, upon the authority of the best modern authors, consirmed by my own experience and observation, that the *lukewarm bath*, between 84 and 96° of Fahrenheit's thermometer, rather more than new-milk warm, is, upon an average, the most suitable temperature. An erroneous notion too much prevails, that the

54

good effects of bathing are principally to be ascribed to the cold bath. The use of any bath, indeed, whether cold or warm, that is, the ftimulating impression excited by the water, is, of itself, an excellent tonic, serving to brace and invigorate the whole fystem. Not to mention the comfortable sensations, that must necessarily attend the cleansing and opening fo many millions of porcs, with which the skin is provided, it is farther remarkable, that water, formerly considered as a simple element, is now pretty generally understood to be a compound body, consisting of oxygen and hydrogen, or vital and inflammable air, the former of which, it is well known, promotes the process of respiration, and literally feeds the vital principle in the human body. Although this affertion rests chiefly on an hypothetical foundation, so much is certain, that a lukewarm bath, used for the legs alone, is found by experience to communicate new spirits to the weary traveller, almost instantly to remove the sense of languor, and to re-animate all his faculties. Bruce, the Abyssinian traveller, remarks, that in the intense heat of that country, a lukewarm bath afforded him more refreshment and vigour, than a cold one. We ought farther to confider, that infants are accustomed scarely to any other than a warm temperature. The cold bath belongs to the class of beroic remedies, and in its fudden and vehement effects nearly refembles electricity. It is moreover an axiom in medicine, that the means of stimulating and corroborating the system,

should be in proportion to the degree of vital power in the individual; that a faint spark may be extinguished rather than kindled by too violent a concussion of air; and that a degree of stimulus and invigoration, which agrees with a firm and robust body, may prove destructive to one that is weak and tender. It might therefore be extremely hazardous to employ a remedy, in the delicate frame of infants, which even adults should not refort to without the greatest precaution. I prefume to go a step farther, and do not hefitate to fay, that the use of the cold bath, as far as relates to the treatment of children, is even DANGEROUS. Its principal mode of operation is by contracting the whole furface of the body, and by causing a general repulfion of the fluids towards the internal parts. Hence in a young and infirm body, which has very little internal reaction, the necessary confequence of cold bathing will be an unequal distribution of the sluids, a partial or local flagnation of them; and, what is worst of all, an accumulation of humours in the head, by which infants are frequently injured, before it is in their power to complain.—The lukewarm bath, on the contrary, produces an uniform revolution and falutary purification of all the fluids. For these reasons, I consider the tepid bath as in every respect preferable, since it may be used somewhat cooler for strong children, or warmer for those of a weakly constitution, and the requisite degrees of heat be regulated according to the increasing age and Arength of the child. In fummer, the water

intended for bathing ought to be expoled the whole day to the rays of the fun, which will impart to it an agreeable and congenial warmth. Rain, or river-water, is the most proper for this purpose; but if there be a neceflity for using spring or well-water, it should be previously foftened with a fmall quantity of boiled water, in which a quarter of an ounce of foap has been dissolved, with the addition of a little bran or oatmeal; or if milk can be had, it will be found a still more useful ingredient. Here I would particularly recommend not to boil the whole quantity of the water to be used for bathing; as it would in that case be deprived of its aërial constituents, which are not without their importance in the bath.—During the first weeks and months, the child should not be suffered to remain in the bath longer than five minutes, which time may be gradually increased to a quarter of an hour. During the whole process of bathing, the body flould not remain inactive, but be gently rubbed with the hand, and afterwards cleaned with a foft spunge. It is of confequence to attend to the point of time, when the child is taken out of the bath; for in almost every instance where warm bathing difagrees with the child, it will be found owing to neglect in not wiping and drying the body with fufficient expedition at this particular period. Hence it is highly necessary to keep warm cloaths in readiness, in which the child should be wrapped up, and dried, the very moment it is taken out of the bath. Every one in the habit of bathing must have

observed, that the evaporation of water on the skin excites penetrating and uncomfortable sensations of cold; and there is an astonishing difference of temperature between actually being in the water, and having water on the skin after quitting the bath. If, therefore, a child, from want of due precaution, be kept for several minutes with a naked, wet body, it will be liable to contract a cold, the more dangerous in its consequences, as it immediately succeeds a state, in which the body is warm and the skin open.

It should be further observed, that bathing, immediately after a meal, or with a full stomach, is highly improper, if not dangerous, both in children and adults; nor is it advisable, in rough weather, to carry a child into the open air too soon after bathing. The most proper time for using the bath is the evening, when the child can be removed to

bed, as foon as it is completely dried.

There is another species of bath, equally indispensable, which I will call the Air-bath; or the daily enjoyment of fresh air. This is usually considered as a promenade, or walk of pleasure; and as children cannot judge of its great utility, and the weather is not always favourable for excursions, parents are sometimes guilty of unpardonable neglect, in consining infants for whole days and weeks together within their rooms. But if air be essentially requisite to animate the most subtle powers of man, it follows, that it is as necessary to the organs of life as food and drink; and that its salutary influence on the consti-

tution does not fo much depend on the state of it with respect to pleasantness and serenity, as on its freshness and constant renewal. Herce I would impress it on the reader, as a rule not to be departed from, to let no day elapse, without affording the child an opportunity of imbibing the Salubrious qualities of fresh air. In the first months great precaution is necesfary, and children born in fpring or fummer have in this respect no small advantages, as there is less danger in exposing them to the open air during the warm months, than there is in autumn and winter. In the milder feafons, too, violent winds, and moist weather, cannot be too carefully avoided. After the two first months of its existence, if the child has been duly habituated to fresh air, it may be fafely carried out in any state of the weather: this ought to be regularly done every day, if it be only for half an hour, as it is one of the most nourishing cordials that can be given. I shall just notice here, in a cursory way, the great benefit which the eyes of children derive from this practice, and which, particularly at a time when complaints of weak and fore eyes are heard in almost every family, is of the utmost importance. It is an unquestionable fact, that the shortness of fight, and weakness of the eyes, so prevalent among the inhabitants of towns, is chiefly owing to the injudicious custom of confining children, during the first years of their lives, almost constantly within four walls; so that the eye. being accustomed to near objects only, becomes organized for a narrow view, and at length is rendered incapable of forming the focus properly for diftant objects. On the other hand, it is equally certain, that by an early and daily exertion of the organs of fight, in behold in remote objects, in the open air, the circle of vision is enlarged, the power of fight in reased, and a folid foundation laid for acquiring a clear and comprehensive differen-

ment of objects.

From the preceding observations, it will be readily admitted, that the proper and daily airing of the nursery, in winter as well as in fummer, is of no finall importance to the wellbeing of children. It has been proved by many fatal instances, that a confined and impure air is of itself capable of exciting the most violent convultive fymptoms, and confequently is one of the principal causes, that so many infants die of convulsions, during the first months of their lives. Would it not be more eligible, to felect the most airy apartment in the house for a nursery, than low and confined garrets, as is too frequently the case in large families? The room, in which children breathe, should at least be capacious and lofty, and exposed to the cheering rays of the fun, which not only influence the temper and spirits of children, but serve to purify the corrupted air in their apartments.

Persons unaccustomed to restect on this subject, can scarcely conceive, what salutary effects the simple means here recommended, namely, the early habit of washing, bathing, and daily airing, produce on the constitution, and physical formation of the child. The

habit of body, growth, and appearance of children, properly educated in this respect, will be totally different from those, who are reared like foreign plants in a hot-house. To point out still more forcibly the peculiar advantages attending the regimen here recommended, I shall exhibit a picture of such children, not taken from fancy, but authorized by facts, and according with the experience of many modern observers, as well as my own, and that of a respectable physician in Germany, Professor Huseland of Jena, to whom I am greatly indebted for the following observations:

1. A child thus treated is more hardy and less affected by the viciflitudes of climate and weather.

2. Its body is ftraight and robust; its limbs are uniformly muscular, and well proportioned.

3. The stages of evolution, in its different organs, take place in regular succession;—no power, no capacity, outstrips another; its teeth do not appear too soon, nor at irregular periods; the child does not begin to walk too early nor too late; and the same order is observable with regard to its speaking. Even the mental faculties expand themselves more regularly, that is, not too rapidly, but after the most important bodily changes have been effected. Every period of its progress to maturity comes on in a natural and gradual manner, so that the child, in a pil sical sense, longer remains a child;—he does not shoot up into manhood, before he has completed

the proper term of youth; and thus every stage, as well as the whole career of his ex-

istence, is considerably prolonged.

4. By this treatment the circulation of the fluids, and all internal motions, particularly of the lungs and intestines, together with the usual evacuations, are beneficially promoted. Of no less advantage is the bath to those children, that are subject to habitual costiveness; a distemperature which cannot be too much guarded against, not only during the age of childhood, but also through the whole life. Infants accustomed to the bath, and fresh air, are scarcely ever known to suffer from this complaint.

5. The texture of their muscular sless becomes folid, the colour blooming, and the body neither appears tumid and spungy, nor parched and meagre. The complexion is lively and fresh;—the head and lower belly are in just proportion to the rest of the body, and the disposition to rickets, so common in

children, is not perceived in them.

6. Neither are fuch children as enjoy the benefit of the bath affected by that excessive sensibility and diseased irritability of the nervous system, which in many instances so fatally degenerates into spasms, sits, and convulsions. These irregularities, in early life, are chiesly instrumental in bringing on that pitiable state, in which some unhappy persons, through the whole of their lives, are little better than loco-motive nervous machines—organized beings, that exist apparently for the sake of seeling only, not for acting.

C

7. Diseases of the skin, eruptions, catarrhs, coughs, obstructions of the first passages, &c. are rarely observed to attack a child properly treated; and if they do, their duration will be short, and the crises easy and natural.

8. Those diseases in children, which are commonly called dangerous, as the small-pox, measles, scarlet sever, &c. and which are ultimately diseases of the skin, are greatly alleviated in their symptoms, and more easily overcome, when the skin is in full health and vigour;—but as the usual management of children deprives the skin of those properties, we need not be at all surprised at the danger and subsequent mortality of children, in the abovementioned diseases.

9. The early practice of washing and bathing may be also recommended, as tending to threngthen that sense of cleanlines, which is so praiseworthy and useful in itself; and which is not sufficiently cultivated among those nations, where the bath is in disuse.*

If the means above flated are expected to produce their full effect, it should not be forgotten, that the whole management of the child ought to correspond and keep pace with

^{*} The Russians, notwithstanding their ignorance, and rusticity of manners, take the lead of the more refined French and Germans, both in a delicate sensibility of cleanliness, and in the practical use of the bath. I lately read of a foreign gertleman, travelling in Russia, who had hired one of the ratives as his groom or pessiblion. After having travelled several days tog ther in very suitry weather, the semi-barbarian upon his knees requested his employer to grant him leave of absence for two or three hours, to resresh himself with the luxury of a bath, which to him was indispensable, and the want of which he had long felt. The profants in that country possess a resinement of series, with respect to the surface of the body, with which the next elegant ladies in other countries seem totally unacquainted.

the preceding practice. Without attending to this condition, conftant washing and bathing may not only prove of little service, but may in some instances be productive of mischief. Hence it is absolutely necessary to prohibit the use of feather-beds, cumbersome dresses, &c. and to avoid all suffocating rooms, whether occasioned by too great heat, or an

offensive corrupted atmosphere.

There is no practice more detrimental to the powers and energy of man, in the first period of his evolution, than that of immediately finking the tender infant in a fost feather-bed. In this situation, all the organs become extremely relaxed, and we lay the foundation of a very serious malady, a sweating-skin; the source of constant colds, tooth-achs, head-achs, catarrhs, and innumerable other

complaints.

For these and similar reasons, I would advise parents to lay their children, from the very hour of their birth, on foft and cooling mattreffes, under thin blanket covers, or cotton quilts, which do not incommode the body, leave the hands and arms at liberty, and are not liable to excite too great a degree of heat. In the intense cold of winter, an additional blanket may be used, which, however, should be removed when the weather turns milder, and the child grows stronger. But the greatest mischief arises from bolsters or pillows filled with feathers; which must, after a certain time, produce uncleanliness and a disagreeable smell. Such a pillow is calculated to collect and retain mephitic vapours; and for this obvious reason it cannot but be unsafe to sleep for a whole twelvemonth with one's head reposed on such a mass of acrid exhalations. This inconvenience may be easily avoided, by furnishing children with cushions silled with horse-hair, or with the softest bran, previously well beaten; the best for this purpose is the bran of oats. The great advantage of these pillows is, that they admit moiture to pass through them, consequently they will always remain dry; and may from time to time be renewed, while they preserve a moderate and regular degree of warmth.

Cleanliness, in domestic life, is one of the cardinal virtues, and an effential requisite to the proper physical education of children. Indeed, I cannot help remarking, that this is perhaps the only province of parental care, in which we never can do too much. For this end, we ought not to neglect the article of linen, as the frequent change of it is of more consequence than many parents are aware of. A child is much more liable to perspire than an adult; the natural effect of which is, that its linen is more readily foiled and rendered unfit for wearing. I would therefore advise all parents, who can afford it, to give their children clean, dry linen every day. An undoubted proof of the utility of this practice is, that instances have occurred of children being cured of the rickets, when, from the first appearance of that complaint, they have been daily furnished with clean linen, well dried, and occasionally smoked with juniper-berries, frankincense, or other persuming substances, in order to expel the moisture, which is absorbed by linen. But if a clean change cannot be conveniently had every day, the night-shirt as well as that of the day, ought to be regularly dried, and perfumed if neces-

fary.

Lastly, let the dress of children be light; the head and breast during the first months may be covered, though very slightly; but as soon as the hair is sufficiently strong to afford protection, there is scarcely any necessity for hats or caps, unless in rainy or cold seafons. The breast and neck too acquire more firmness, and are rendered hardier, by keeping them uncovered; as our frequent colds and fore throats chiefly originate from the absurd habit of wearing bosom-friends and stiffened cravats.

I shall conclude these observations with an historical account from Herodotus, which clearly illustrates the advantage attending the cool regimen of the head. This judicious and learned writer informs us, that after the battle fought between the Persians, under Cambyses, and the Egyptians, the slain of both nations were separated: and upon examining the heads of the Persians, their skulls were found to be so thin and tender, that a small stone would immediately persorate them: while on the other hand, the heads of the Egyptians were so firm, that they could scarcely be fractured by the largest stones. The cause of this remarkable difference Herodotus ascribes to a custom the Egyptians had of shaving their heads from the earliest infan-

cy, and going uncovered in all states of the weather; whereas the Persians always kept their heads warm, by wearing heavy turbans.

I fincerely wish, that the rules and observations, here fubmitted to the candid reader, were more generally understood and practi-fed, so far at least as they are found to accord with reason and experience. I am not however disposed to imagine, that plans of fudden improvement are the most likely to succeed; and I am well aware of the difficulties we must expect to encounter, when we attack old and rooted prejudices, with the hope of vanquishing them all at once. For though I should be fortunate enough to substitute founder opinions and better practices, in lieu of those already established, yet, unless the mind be prepared for fuch changes, by a proper philosophic culture, nothing is more probable, than that a speedy relapse into former errors will be the necessary consequence. The history of our own time has, in some recent instances, evidently confirmed the truth of this observation. We find even the mandates of arbitrary power infufficient to produce a thorough reform in the manners and customs of a superstitious people. The philanthropic but weak emperor Joseph II. was obliged to yield to the torrent of popular prejudice; and, in spite of his better reason, frequently to repeal measures dictated by the enlightened genius of philosophy. His obsti-nate and infatuated subjects were not fully ripe for such salutary innovations. Our age is fearcely docile enough to purfue those improvements, which a rapid and continual progress in the sciences is daily suggesting. Upon this ground alone we can explain the frequent and obvious contrast between the prevailing theories and practices, both in the higher and lower walks of life. A great majority of the common people, from their habitual indifference to literature, and their aversion to serious reflection, still manifest their ancient prejudices to every thing which falls under the description of novelty or improvement. More than one generation will probably elapse, before even a part of the useful hints can be realized, which lie dispersed in the later writings on subjects of health and domestic economy. Whatever benefits can be attained by popular instruction, both with regard to the treatment of children and adults, must be introduced in a gradual manner, The ancient treatment of children, being confecrated by time, must not be rudely and precipitately rejected; but old customs may bechanged by prudent and moderate management; and thus we may proceed from one step to another, in extending the boundaries. of truth and reason. A gradual transition from a faulty to a better state of things, is commonly the most permanent. Let us combat, at first, the most dangerous notions and prejudices: the conquest over a fingle prejudice, if it be completely extirpated, is a triumph of no little moment; inafmuch as it will shake the foundation of many others, more or less connected with it.

In my earnest endeavours to caution the reader against inveterate prejudices, I do not mean to infinuate, that a perfect and permanent state of health is compatible with the delicate organization and complex functions of the human body: I am well aware, that its most healthy condition closely borders on disease, and that the seeds of distempers are already planted in the very fulness or luxuriance of our fluids. Hence no absolute perfection is to be found among mortals, whether we confider them in a phyfical or moral state. CICERO illustrates this polition, when speaking of man as a moral agent, with equal truth and energy, in the following words: "He is not," fays this philosophical orator, "the most virtuous man, who commits no faults; but I consider him as the most virtuous, whose conscience reproaches with the fewest."

CHAP. I.

A Practical Inquiry into the means and plans adopted among different nations, with a view to prolong human life.—An historical survey of this interesting subject, in different ages; together with the success which has attended the respective efforts made by nations and individuals.—A brief statement of the conditions requisite to the attainment of a long and healthy life.—Observations, rules, and cautions deduced from the experience of ages.—Symptoms of actual dissolution.—Summary account of a dietetic system; explanation of its design, and the wast diversity of objects comprehended under this popular science.

As the enjoyment of 'a found mind in a found body' is one of the greatest of terrestrial blessings, it is incumbent on every rational inquirer, to devote some portion of his time and industry to the research of such useful and practical objects, as may contribute to improve and insure so desirable a state.

As long as the various functions of the human body, the voluntary as well as the involuntary motions, are performed with ease, and fusfer no interruption, we usually pronounce the body to be in a state of health; in the contrary case we call it diseased. I shall advance a step surther, and affert, that when we do not seel ourselves encumbered with the

weight of our own frame, and when we are not disposed to reslect, with uneasiness and solicitude, upon its physical condition, then we have a right to confider our health as being

in a perfect state.

Although we are liable to fuffer from the attacks of disease, in a variety of shapes, yet we have abundant reason to contemplate with fatisfaction the chequered condition of human life: for, even in the present impersect state of things, we find comforts more than fushcient to counterbalance our forrows. Confidering the innumerable accidents, to which we are daily and hourly exposed, it is a matter of just furprise, that frail, imbecile man should remain in health during the greater part of his life; and still more so, that, upon an average, the number of healthy individuals should be found far to exceed those in a contrary state. If we further advert to the want of thought and circumspection, which marks the conduct of man in general, in the treatment of his body, our aftonishment will necessarily increase, that he so often escapes the dangers prepared by his own hands. But parental Nature frequently repairs the injury, though we are not conscious of her faiutary efforts. She powerfully co-operates, when art is called in aid, to restore that harmony and order in the fystem, which had been imprudently or inadvertently disturbed. To her healing powers we are principally indebted, if the fufferings refulting from ignorance or obstinacy are less severe, than the extent of the mischief seemed to portend.

It cannot be expected, that perfons unacquainted with the economy of the human frame should be able to discriminate between internal and external causes, and their effects. Where a competent share of this knowledge is wanting, it will be impossible to ascertain, or to counteract, the different causes by which our health is affected; and should a fortunate individual ever six upon a suitable remedy, he will be indebted to chance alone for the

discovery.

This has been the case in all ages, and alas! it is still deplorably the case. Remedies have from time to time been devised, not merely to serve as Nostrums for all diseases, but also for the pretended purpose of prolonging human life. Those of the latter kind have been applied with a view to refift or check many operations of nature, which insensibly consume the vital heat, and other powers of life, fuch as respiration, muscular irritability, &c. Thus, from the implicit credulity of fome, and the exuberant imagination of others, observations and experiments, however discordant with found reason and philosophy, were multiplied, with the avowed defign of establishing proofs or refutations of this or that abfurd opinion. In this manner have fanaticitin and imposture fulfified the plainest trutt..., or forged the most unfounded and ridiculous claims; fo that one glaring inconsistency was employed to combat another, and folly fucceeded folly, till a fund of materials has been transmitted to posterity, fufficient to form a concise history of this Jubject.

Men, in all ages, have fet a just value on long life; and in proportion to the means of enjoying the same, this value has been felt in a greater or less degree. If the gratification of the fenfual appetite formed the principal object of living, the prolongation of it would be, to the epicure, as desirable, as the prospect of a life to be enjoyed beyond the limits of the grave, is to the moralist and the believer.

In the Old Testament, the promise of a long life was held up as one of the most important fources of confolation: and, conformably to the principles of Christianity, a patient continuance in well-doing, or, in other words, a long life rich in good works, can best insure the hope of a more happy state in a future world. Hence the wish of a speedy terminition of our existence here, is one of those eccentricities, into which only perfons deprived of reason are liable to be drawn, either from extreme anxiety, or the want of mental fortitude. The defire of longevity feeins to be inherent in all animal life, and particularly in human nature: it is intimately cherished by us, throughout the whole of our existence, and is frequently supported and strengthened, not only by justifiable means, but also by various species of collusion.

The possibility of prolonging human life was never doubted by the Orientals, even in the earliest ages. One of the most ancient methods on record, is that of placing the aged and decrepit in the vicinity of an atmosphere, replete with the exhalations of blooming youth. It is not improbable, that a certain

cultom then prevailing in the East, by alluring the fancy with beautiful images, and by impoling upon the understanding through poetical fictions, first induced man to entertain this fingular notion. The bloom of a juvenile age, and particularly the healthful virgin, was compared, by the Orientals, with roses, lilies, and other elegant flowers; she was introduced in allegorical description, to reprefent odoriferous spices, balms, and oils, and was made the subject of pastoral and other poems. How eafy, then, the transition from fancy to belief, that the exhalations of vigorous and healthy perfons must be highly conducive to the support of exhausted age; that they were capable, like the fragrant balms of the East, of softening the rigidity of the sibres, of exciting the vital spirits, and, in short, of supplying the aged with a fresh stock of health. The history of King David furnishes us with a striking illustration of this renovating process.

In the writings of the ancient physicians, we meet with various accounts, from which we learn, that this method has ever been a fivourite refource of invalids, worn out with age. Modern physicians also mention the practice, and the celebrated Boerhaave informs us, that he advised an old and decrepit burgomaster at Amsterdam to sleep between two young persons; and that his patient, who before was sinking under the weight of infirmities, obviously recovered strength and

cheerfulness of mind.

The great age of fome schoolmasters has

likewise been ascribed to the benesit they derive from breathing, almost constantly, among young and healthy children. It has been farther observed, that young persons, if they fleep in company with the aged, become lean and enfeebled.—Upon more accurate inquiries, however, it is pretty evident, that most of the benefits (perhaps all of them) which the aged derive from this expedient, may be placed to the account of the imagination, and its furprising effects on the body. It is this power which, in my opinion, renews the languishing flame of the aged, and which may preserve them for some time longer in that renovated state, provided it be supported by a proper attention to diet and other circumstances.—We frequently see a debilitated and peevish old man assume a complacent smiling aspect, when a sprightly maiden addresses him in the language of courteous pleafantry. The most charming images recur to his stimulated imagination; and the powers of life are, as it were, again roused, and directed to one object. That fuch means of reanimating old! age, may have a favourable effect on health, cannot be disputed.

To imagine, however, that the vigour of health and the bloom of youth can be transfused by insensible perspiration, or exhalation, into the body of the aged, is to labour under a very palpable mistake. I shall prove, in the next Chapter "On Air and Weather," that every living being necessarily corrupts the air more or less by its respiration; and that the atmosphere, thus impregnated, be-

comes unfit for other beings to breathe in; because every expiration contains certain particles, which are separated by the lungs, as being useless and noxious to the body. How then is it conceivable, that matters or substances should be hurtful to one body, if retained in it, and useful to another, if communicated to it? Or was it supposed, that the watery parts of insensible exhalation from the young body, could moisten and refresh the parched sibres of the aged? To accomplish this purpose, we are possessed of remedies much purer and more effectual. Natural warmth or heat is the only means competent to produce such a salutary effect; as that alone is capable of exciting the slumbering energy of life. And in this respect, I apprehend, we ought to do justice to the above-defcribed method practifed by the ancients.

When young persons live or sleep with old people, and are observed to grow thin and infirm, (which however is not always the case) that proceeds from another circumstance, namely, that the former absorb or inhale the noxious particles of the latter; but from this it by no means follows, that the aged body attracts the vital principle from the younger. Although free caloric, or matter of heat, may probably pass over from the young body into that of the aged; yet this transfusion, under certain circumstances, would be rather to the advantage than difadvantage of the, former; inafmuch as this deprivation of supersluous caloric is not unfrequently found to be serviceable and whole-

fome.

From the preceding remarks we may conceive, that a school-room filled with the various exhalations of children, cannot conduce to the prolongation of life; and, consequently, that the great age of certain schoolmasters must be ascribed to some other cause. An accurate account of the mortality prevailing among that class of men would satisfactorily demonstrate, that the age of schoolmasters is in a just proportion to that of other classes of society.

I shall now consider several other plans, that have been adopted for the prolongation

of human life.

The Egyptians, who lived in a country rendered unwholesome by intense heat and frequent inundations, could not long remain ignorant of the comparative longevity of their northern neighbours, the Greeks. After many fruitless attempts to discover the true cause of their short life, and to provide the means of removing that cause, they at length became fanatical enough to imagine themselves possessed of the grand secret for prolonging life-in the constant use of sudorifics and emetics. The air of Egypt, being impregnated with aqueous and putrid particles, not only checked the process of perspiration, but also generated various epidemic distempers. In fuch cases, sudorisse medicines were necessary and proper; and even emetics, by exciting a forcible commotion through the whole fystem, not unfrequently restored the activity of the cutaneous vessels, and thus produced a favourable effect in those mala-

dies. Farther, the heat of the climate inspissated their fluids; this circumstance, connected with their usual mode of life, and their crude articles of food, necessarily brought on an excess of bile, which overflowing the stomach upon the least occasion, could not fail, fooner or later, to occasion very obstinate diseases. The emetics, therefore, being eminently qualified to evacuate the bile, would of course obtain general reputation among the Egyptians. These and the sudorifics were for a long time confidered as specific remedies; from their tendency to expel the matter fo dangerous to life; and because in those ages diseases were considered the only enemies to longevity: the Egyptian physicians and philosophers not being able to diftinguish between effects and their causes, the latter of which existed in the pestitential vapours of a hot climate.

Thus it became a custom to take at least two emetics every month; to inquire of acquaintances and friends, how those medicines had operated, and to wish each other joy upon these occasions. I need not observe, that this singular method of prolonging life is not to be recommended as worthy of imitation; that the periodical custom of taking medicinal remedies renders their frequent repetition necessary, while it destroys their occasional essicacy; and that it therefore chiesly belongs to the department of the physician to determine, when, and in what degree, such

medicines are to be administered.

The Greeks lived in a more romantic and

picturesque country; their conceptions wich regard to the structure and functions of the human frame were more correct and conformable to nature. Their philosophers and physicians were more enlightened and less prejudiced than those of Egypt; they were not, like the latter, under the capricious influence of a wild imagination, too frequently disordered by the effects of BLACK BILE. Nature, displayed in all her charms, in the sublime and beautiful scenery of their country, every where invited them to the enjoyment of free and pure air; the effects of this en their fusceptible nerves, combined with an excellent fystem of bodily exercise, proved the best specific for counteracting the effects of time, and thus prolonging their active, healthful lives. For this great and beneficial purpose, particular methods and rules were contrived, in order to give the body the most varied and effectual, yet gentle motions;these athletic exercises were judiciously adapted to the different constitutions, situations, and ages of life, so that the fagacious Greeks arrived at an extraordinary degree of perfection in the gymnastic art.

The great advantage of fuch a course of bodily exercise cannot be disputed, when we consider how many individuals in all countries die prematurely from want of activity, motion, and nervous energy; though their organization may be in no respect faulty. Besides, a body inured to frequent and laborious exercise, will not be easily affected by external causes of disease; being secured, as

it were, by a coat of mail, against the attacks

of many acute diforders.

The Greeks carried, to a still greater degree, the system of gymnastic motions. By the same method they attempted to cure diseases in their sirst stages, not excepting such as were already formed, and to put a stop to their further progress. They caused the patient to move in various positions; they applied gentle friction to the whole surface of the body; and used different methods to overcome the languor of the muscles, by exciting and stimulating the muscular energy.

In relaxed, weakly individuals, whose organization is desicient in the proper degree of tension or elasticity, this method must be allowed to possess great advantages; but I do not conceive it necessary to prove here, that it cannot be consistently applied to all diseases. It is not to be supposed, that the weary traveller can be either strengthened or

refreshed by additional exercise.

The modern methods of bracing the human body, such as frequent bathing in coldwater, exposing the body to all the vicissitudes of climate and weather, the various modes of supporting bodily fatigue; as travelling on horseback and on foot, &c. which are so indiscriminately recommended to our aspiring youth, cannot in every instance fortify and render the human frame indestructible:—on the contrary, all such violent efforts have a tendency to bring on the symptoms of age, at a much earlier period than it ought to appear; as the joints and much earlier are there-

by rendered liable to contract an uncommon degree of stiffness and rigidity.—To load tender youth with burthens dispropor ionate to their age, and to impose upon them he task of men, can never be the most proper means of hardening and preparing them for a long and active life.

A distinction, however, should be made here, between bracing the sibres, of which all folid parts of the body confift, and bracing the sense of touch or feeling. The animal sibres may be folid, but should not be fo rigid as to become infensible; a certain degree of irritability is necessary to the proper exercise of their contracting and relaxing power. If, further, there should exist in the body a disposition towards rigidity and infensibility, any artificial modes of bracing it will be of dangerous tendency. If, on the contrary, the fibres should be too irritable, the Green method may, in that case, be resorted to with fafety and advantage. A striking instance of this occurs in the history of Captain Cook. On his arrival in the Friendly Islands, he was feized with an acute rheumatifin, attended with excruciating pains. He was foon reneved from this torturing fituation, by the easy and instinctive process of gentle friction, which the Islanders generally followed on fach occasions. Thus a few untutored perfons completely effected what could not have been fooner, nor more eafily accomplished by the systematic art of the learned.

From these considerations we may safely infer, 1. That the cold bath, gymnastic exer-

cifes, bodily fatigue of any kind, and all expedients to brace and invigorate the conftitution, ought only to be adopted under certain limitations, viz. with a proper regard to particular cafes and circumftances: and, 2. That these severe remedies cannot and ought not to be universally nor indiscriminately recommended, as methods of prolonging life.

Let us not, however, disparage the merits of that ingenious race of men, whom we only know from their inimitable works. For, although the method of the Greeks cannot be safely introduced among us, without many and great exceptions, we must do them the justice to allow, that in their operations of hardening the human body, they proceeded in a more cautious, gradual, and judicious manner, than the moderns seem willing to submit to. Sudden changes of any kind produce a fort of revolution in the body, and this is necessarily attended with a waste of strength, proportionate to the violence of the shock.

Plutarch possessed clear and rational ideas on the subject of preserving and prolonging human life; the truth of which he confirmed by his own experience, during a series of many happy years. He advises to keep the head cool and the seet warm, not immediately to take medicines on every slight indisposition, but rather to let Nature relieve herself by fasting a day, and, in attending to the mind, never to forget the body. Much learning is compressed in these golden precepts, which will be valuable as long as hu-

man nature remains the fame. The attention bestowed upon the mind, however lasdable, should not authorise us to neglect the care of the body; the intimate connexion subfifting between both requires a due proportion of care and attention to be pa'd to each. In the fame degree, as a difeafed body fympathetically torments the mind, fo does an infirm mind agitate and harafs the body; and fuch tortures and reciprocal affections are unavoidably attended with the confumption of animal life.-What Plutarch enjoins, with respect to keeping the head cool and the feet warin, is agreeable to reason and experience; we should not, however, imagine, that the grand fecret of prolonging life confifts in the tole observance of these maxims. The head and feet are not the only points, in which life is concentrated; they may indeed have a beneficial or pernicious influence on the whole body, and in this respect they demand a share of our attention; but no other part ought on that account to escape our notice.

I now enter upon a very unpleasant tak, namely, that of reviewing a period of darkness, during the barbarity of the middle ages, when the progress of true knowledge was obstructed by the most absurd fancies and childish conceits; when conjectures, caprices and dreams supplied the place of the most useful sciences, of the most important truths. Chemistry, so essentially requisite to explain the phenomena of known and unknown substances, fell into the hands of jugglers and fanatics;—their systems, replete with philo-

fophic nonfense, and composed of the most crude, heterogeneous materials, served rather to noursh superstition than to establish facts and illustrate useful truths. Universal remedies, in various forms, met with strenuous advocates and deluded consumers. The path of accurate observation and experiment was fortaken; far from penetrating into the mysterious recesses of Nature, they bewildered themselves in the labyrinth of fanciful speculation; they overstepped the bounds of good sense, modesty, and truth, and the blind led the blind.

The prolongation of life, too, was no longer fought for in a manner agreeable to the dictates of Nature; even this interesting branch of human pursuits was rendered subservient to Chemistry, or rather to the confused fystem of Alchemy. Original matter was looked upon to be the elementary cause of all beings; by this they expected literally to work miracles, to transmute the base into noble metals, to metamorphole man in his animal flate by chemical process, to render him more durable, and to fecure him against early decline and dislolution. Millions of vessels, retorts, and phials were either exposed to the action of the most violent artificial heat, or to the natural warmth of the fun; or elfe they were buried in some dunghill, or other fetid mass, for the purpose of apprehending this original matter, or obtaining it from putrescible subftances.

As the fubstance called Gold always bore the highest value among metals, these mongrel philosophers concluded, from a ridiculous analogy, that its value, with respect to the preservation of health, and the cure of difeases, must likewise surpass that of all other remedies. The nugatory art of dissolving it, so as to render it potable, and to prevent it from being again converted into metal, employed a multitude of bufy idiots, not only in concealed corners, but in the splendid laboratories of the palaces of the great. Sovereigns, magistrates, counsellors, and impostors, were struck with the common frenzy, entered into friendship and alliance, formed private fraternities, and sometimes proceeded to fuch a pitch of extravagance, as to involve themselves and their posterity in ruinous The real object of many was, doubtless, to gratify their avarice and desire of aggrandifement, although this finister motive was concealed under the specious pretext of searching for a remedy, that should serve as a tincture of life, both for the healthy and diseased; yet fome among thefe whimfical mortals were actuated by more honourable motives, zealous only for the interests of truth, and the wellbeing of their fellow-creatures. The common people in fome countries, particularly Italy, Germany, and France, often denied themselves the necessaries of life, to save as much as would purchase a few drops of the tincture of gold, which was offered for fale by some superstitious or fraudulent chemist: and fo thoroughly perfuaded were they of the efficacy of this remedy, that it afforded them in every instance the most considert and

enly hope of recovery. These beneficial effects were positively promised, but were looked for in vain. All-subduing Death would not submit to be bribed with gold, and Disease resused to hold any intercourse with that powerful deity, who presides over the trade and commerce of nations.

As, however, these diversified and almost numberless experiments were frequently productive of useful inventions in the arts and manufactures; and as many chemical remedies of real value were thereby accidentally discovered, the great and general attention to those bold projectors, was constantly kept alive and excited. Indeed, we are indebted to their curious operations, or rather perhaps to chance, for feveral valuable medicines, the excellence of which cannot be disputed, but which, neverthelefs, require more precaution in their use and application, and more perspicacity and diligence in investigating their nature and properties, than the original preparers of fuch articles were able or willing to af-

All their endeavours to prolong life, by artificial means, could not be attended with beneficial effects; and the application of the remedies thus contrived, must necessarily, in many cases, prove detrimental to the health of the patient. In proof of this affertion, it will be sufficient to give a slight sketch of the dinferent views and opinions of the Goldmakers, Rosencrucians, manufacturers of Astralian Salts, of the Drops of Life, and Tinctures of Gold, hunters after the Philosopher's Stone.

&c. &c. Some of these enthusiasts fancied life to resemble a slame, from which the body derived warmth, spirit, and animation. This slame they endeavoured to cherish and to increase by their remedies, supplying the body with materials to feed the same, as we pour

oil into a burning lamp.

Others imagined they had discovered something invisible and incorporeal in the air, that important medium in supporting the life of man. They pretended to catch, to refine, and so to reduce and materialize this undefinable something, that it might be swallowed in the form of powders or drops; that by its penetrating powers it might infinuate itself into the whole animal frame, invigorating and qualifying it for a longer and healthier duration than usual.

Others again were foolish enough to cherish a notion, that they could divest themselves of the properties of matter during this life; that in this manner they might be defended against the gradual approaches of dissolution, to which every animal body is subject; and that thus fortified, without quitting their terrestrial tabernacle, they could associate at pleasure with the inhabitants of the spiritual world.

The Sacred Volume itself was interpreted and commented upon by the Operators and Alchemists, with a view to render it subservient to their interested designs. Indisputable historical facts, recorded in this invaluable book, were treated by them as hieroglyphical symbols, which contained chemical processes:

and the fundamental truths of the Christian religion were applied, in a wanton and blafphemous manner, to the purposes of making

Gold, and distilling the Elixir of Life.

The productions of Alchemy, far from anfwering the purpose of prolonging life, have rather a contrary tendency. All the remedies which it affords, are of a heating and stimulating nature. The person who takes them will feel himself more cheerful for some time, and on that account he may fancy himfelf more vigorous and juvenile; as they certainly give an additional impulse to the sensations of life, like wine, spirits, and all other stimulants. But this increase of the fensation of life should by no means be confounded with an increase of the power of life. It may be even fafely affirmed, that by the increase of vital fensations, the career of life itself is accelerated, and the confumption of it fooner exhausted; consequently the duration of the body is necessarily shortened.

I should not omit to mention, that these remedies strongly increase the sensitive power of man, they predispose him to sensual pursuits, stimulate him to commit excesses of every kind, incite him to take continual or excessive exercise, as dancing, and the like, and thus by inevitable consequence hasten the waste and dissolution of the body. That, for instance, which, according to the natural course, ought to be expended or consumed in three days, is dissipated perhaps in as many jovial hours. This premature loss is attended with relaxation, irksomeness, and even

aversion to life, till a new dose of stimulants reproduces the former false vivacity. It fares with the patient here, as it does with the hard drinker, who trembles in the morning that follows his nightly debauch, seels his whole frame relaxed, inactive and torpid, and is in a manner obliged to take a fresh dram of his favourite liquor, before he can enter on any serious business, with pleasure or effect.

These famous essences, balms, tinctures of life, &c. are farther dangerous, as they contract the small vessels, so necessary to the preservation of life, as well as to the reparation of the loffes fustained, and thus render them unfit to perform their offices. Hence arise rigidity or stiffness, and exsiccation; the body shrivels, and the symptoms of old age appear at an earlier period than they would otherwise have done. Man is seldom unprovided with the supplies of vitality; -every draught of air we inhale, and every particle of food we swallow, is a fresh accession to the stock of life. But as soon as the fusceptibility or power of receiving those supplies becomes languid, we then may be confidered as unfit to perform the functions of life; and all the medicaments of nature and art will be found infussicient to relieve us. He who searches for the fupplies of life in alchemical productions, elixirs, balfamic effences, &c. will fooner or later, but always prematurely, experience the want of susceptibility. Even that impudent boaster and celebrated insurer of lives, Theophrastus Paracelsus, although he pretended to have in his possession the

stone of immortality, died—in his siftieth year! His vegetable sulphur was a heating and stimulating remedy, partly similar to the

Anodyne Liquor of Hossinann.

The world of spirits also was invaded, and fummoned, as it were, to contribute to the prolongation of human life. Spirits were supposed to have the rule of air, fire, earth, and water; they were divided into particular classes, and particular services ascribed to each. The malevolent spirits were opposed and counteracted by various means of prevention: the good and tutelary were obliged to fubmit to a fort of gentle, involuntary servitude. From invisible beings were expected and demanded visible means of assistance-riches-health-friends-and long life. Thus the poor spirits were profanely maltreated, nay they were fometimes punished, and even miserably flogged in esligy, when they betrayed symptoms of disaffection, or want of implicit loyalty.

As men had thus, in their weakness and folly, forsaken the bounds of this terrestrial sphere, it will easily be believed, that with the help of an exuberant imagination, they would make a transition to the higher regions—to the celestial bodies and the stars, to which indeed they ascribed no less a power than that of deciding the destinics of men, and which, consequently, must have had a considerable share in shortening or prolonging the duration of human life. Every nation or kingdom was subjected to the dominion of its particular planet, the time of whose

1. 2.

government was determined; and a number of ascendant powers were sictitiously contrived, with a view to reduce under its influence every thing which was produced and

born during its administration.

The professors of astrology appeared as the confidants of these invisible rulers, and the interpreters of their will; they very well un-derstood the art of giving a respectable ap-pearance to this usurped dignity. Provided they could but afcertain the hour and minute of a person's birth, they confidently took upon themselves to predict his mental capacities, future viciflitudes of life, diseases, together with the circumstances, the day, and the hour of his death. Not only the common people, or the less informed classes of society, but the most respectable men for learning and abilities, nay even those of the highest rank and station, did homage to those "gods of their idolatry," and lived in continual dread of their occult powers. With anxious countenances and attentive ears, they listened to the effusions of those self-appointed. oracles, which prognosticated the bright or gloomy days of futurity. Even phylicians were folicitous to qualify themselves for an appointment no less lucrative than respectable:they forgot, over the dazzling hoards of Mammon, that they were peculiarly and professedly the pupils of Nature. The curious student in the Universities found every where public Lecturers, who undertook to instruct him in the profound arts of divination, chiromancy, and the famous cabaia.

Not to mention other instances, I shall cite that of the noted Thurneisen, in the last century, who was invelted at Berlin with the respective offices of Printer to the Court, Bookfeller, Almanack-maker, Aftrologer, Chemist, and First Physician. Messengers daily arrived from the most respectable houses in Germany, Poland, Hungary, Denmark, and even from England, for the purpose of consulting him respecting the future fortunes of new-born infants, acquainting him with the hour of their nativity, and foliciting his advice and directions as to their management. Many volumes of this fingular correspondence are still preserved in the Royal Library at Berlin. The business of this fortunate adept increased so rapidly, that he found it necessary to employ a number of fubaltern assistants, who, together with their master, realized considerable fortunes. He died in high reputation and favour with his superstitious cotemporaries; and Thurneisen's Astrological Almanack is yet published in some of the less enlightened provinces of Germany. But it may be asked, how it happens, that an art which determines the fate of mortals, and afcertains the impaffable limits of human life, can at the fame time ferve as the means of prolonging it? This I shall now proceed to account for. The teachers of divination maintained, that not only men, but all natural bodies, plants, animals, nay whole countries, including every individual place and family, were under the government of fome particular planet. As foon as the mafters of the occult science had discovered, by their tables, under what constellation the misfortune or distemper of any person originated, nothing further was required, than that he should remove to a dwelling ruled by an opposite planet, and consine himself exclusively to such articles of food and drink, as were under the influence of a different star. In this artissicial manner, they contrived to form a system, or peculiar classification of plants, namely, lunar, solar, mercurial, and the like—and hence arose a consused mass of dietetic rules, which, when considered with reference to the purposes of health, cleanlines, exercise, &c. form a remarkable contrast to those of the Greeks.

Neither was this preventive and repelling method confined merely to perfons fuffering under fome bodily diforder. In the case of individuals who enjoyed a good state of health, if an unlucky constellation happened to forebode a severe disease, or any other missortune, they were directed to choose a place of residence influenced by a more friendly star; or to make use of such aliment only as, being under the auspices of a propitious star, might counteract the malignant influ-

ence of its adversary.

It was also pretty generally believed and maintained, that a fort of intimate relation or sympathy subsisted between metals and plants; hence the names of the latter were given to the former, in order to denote this supposed connexion and affinity. The corresponding metals were melted into a common mass, under a certain planet, and were formed into

imail medals or coins, in hopes, and with the firm perfuation, that he who carried fuch a piece about his perfon, might confidently expect the whole favour and protection of the

planet thus represented.

The transition from one degree of folly to another is enfy; and this may help us to account for the shocking delusions practifed in the manufacturing and wearing of metallic amulets of a peculiar mould, to which were attributed, by a fort of magic influence, the power and protection of the planet, to whom they related: these charms were thought to possess virtue sufficient to overrule the bad effects prefaged by an unlucky hour of birth, to promote to places of honour and profit, and to be of potent efficacy in matters of commerce and matrimony. The German foldiers, in the dark and superstitious ages, believed, that if the figure of Mars, cast and engraved in the fign of the Scorpion, were worn about the neck as an amulet, it would render them invulnerable, and infure fuccess to their military enterprizes: hence amulets were found upon every foldier, either killed in battle or taken prisoner.

But let us quit a fubject which excites difgust, as it exhibits such glaring deviations from reason and truth. It is much more pleasant to dwell upon examples, which asford satisfactory proof, that the human minds has never been entirely and universally debased, and that there have always existed some individuals, though sew in number, who would not submit their necks to the voke of popular prejudice, and whose superior talents and virtues rescued them from the impositions of general folly or depravity. A memorable instance of this rare merit is to be found in the noble Venetian Lewis Cornaro, whose history illustrates this agreeable and instructive truth, that nature, left to herself, or, in other words, a properly chosen mode of life and diet, regularly persisted in, will achieve great things; and that a frame, disordered and even reduced to a state bordering on the grave, may yet be re-established, and preserve its health and vigour for a great number of

years.

Cornaro had been a professed epicure and libertine, till he entered into the fortieth year of his age. His constitution was so far reduced by the colic, rheumatic pains, fevers, &c. that his physicians at length gave him up, assuring him he could not survive much longer than two months; that no medicines whatever could avert this catastrophe, and that the only possible means of preserving his life would be a regular adherence to a frugal diet. He punctually followed this advice, perceived fymptoms of convalescence within a few days after entering on his plan of reformation, and, after the lopfe of twelve months, was not only completely restored, but found himfelf in a better state of health than he had ever been during any period of his life. He resolved therefore to confine himfelf to a ftill more parlimonious regimen, and to take nothing more than what he judged to be absolutely requisite for his support. Thus, during fixty years, he confined himself to exactly twelve ounces of food a day, (bread and other nourishment included) with thirteen ounces of beverage. It should be also observed, that during this long period he carefully avoided violent heat, cold, passions, and extremes of every kind; and by rigidly and uniformly adhering to this moderate diet, not only his body, but his mind also, acquired fo determined a tone, that no common incidents could affect them. At a very advanced age he loft a law-fuit, which involved pecuniary concerns of great importance, and on account of which two of his brothers died of broken hearts; but he still retained his pristine health and tranquillity. His carriage happening on some occasion to be overfet, he was dragged by the horfes, in confequence of which his arms and legs were diflocated. He caused them, however, to be reduced again, and, without taking any medicines, we find him in a short time restored.

A striking instance of the dangerous effects likely to attend the slightest deviation from long custom and habit, is the following: When Cornaro had reached his eightieth year, his friends prevailed upon him to add a small portion to his daily quantum of food; alleging that his advanced age necesfarily called for additional support. Although he was not convinced by this argument, being of opinion, that, with the general decrease of strength, our powers of digestion are likewise impaired, and that we ought to diminish rather than to increase our food, in pro-

portion to the decay of nature; yet he yielded to the folicitations of his friends, and increafed his food from twelve to fourteen. and his drink from thirteen to fixteen ounces. "Scarcely," to quote the words of our diatetic veteran, "had I proceeded in this altered mode of living for ten days, before I found my spirits visibly affected; a fretful, pecvish temper succeeded to my former cheerfulness and gaiety, so that I became a burden to myfelf and others. This change of temper was followed by other fymptoms slill more alarming. On the twelfth day, I was attacked with a pain in my fide, which cortinued for twenty-four hours together, and foon after found myself oppressed by a fever that raged with unabating fury for thirty-five days, to that my life was at times despaired of. By the bleffing of God, however, on returning to my former regimen, I recovered from this shock, and now enjoy, in my eighty-third year, perfect health or body and ferenity of mind. I can mount my horse without assistance; I can climb steep precipices, and but lately I wrote a comedy, abounding with traits of innocent mirth and raillery. When I return home, after being engaged in my private affairs, or from attending the councils of state, I feel inexpressible satisfaction in the company of my grandchildren, cleven in number, whose education, amusement, and fongs, are the comfort of my age. I frequently join them in finging, as my voice is now stronger and clearer than I ever knew it to be in my youth, and as my happiness is not disturbed by the complaints, the moroseness, and discontented humours, so frequent-ly the lot of intemperate old age."

In this happy frame of body and mind, Cornaro attained to his hundredth year; his virtuous and memorable example, however, has hitherto had but few followers. He found by actual observation and experience, that a strict and uniform regimen, or a regular daily allowance of food and drink, ascertained by weight, was the best method he could purfue, for the purpose of prolonging his life. He did not wish however to be understood, nor does it follow in general, that this or any other precise portion of nutriment is to be held out as a proper standard, by which all persons are to regulate their diet. His advice. that we should take no more food than wha. is absolutely necessary to our subsistence, may be thus explained; namely, that the restoration of strength, derived from supplies of nutriment, ought to bear an exact proportion to the losses sustained by the body. He, for in-france, who spends little of his time in bed, and much in the open air, takes frequent exercife, is constantly employed in some laborious occupation, makes long journies on foot or horseback, or the like, will feel himself refreshed and strengthened after partaking of a plentiful meal, and cheering beverage; and fuch a repast is even indispensable to him, to recruit the fources of his muscular strength and activity. If, on the other hand, a person who lounges away half of his time in bed, or upon the sofa, were to consume a quantity of

food equal to the former, he would no doubt feel himself heavy and uncomfortable. Yet here too, the consequent loss of strength may vary in degree, in different sedentary persons; and this circumstance will afford me an opportunity, in the sequel, to apply to individual cases the doctrine suggested by the experience of Cornaro.

There was another period, during which blood-letting came into general use, and obtained great credit, as one of the most effectual means of prolonging life: the superfluity and vitiated state of the blood, or what physicians term a plethoric habit, being looked upon, at the same time, as a principal means of shortening life. Through the veins thus regularly opened, at certain feafons, the fuperfluous or vitiated blood was supposed to be emitted, while that of a more falubrious quality was left behind. Confidered as a medical rerbedy, phlebotomy must certainly be allowed to possess its uses, and it is sometimes a necessary expedient, to produce an immediate diminution in the fulness of the blood, particularly when the time is too fhort, and the danger too pressing, to admit of any other method for effecting that purpose. As there can be no doubt, that blood-letting is an invaluable remedy in many diforders, it is the more peculiarly incumbent on the practical physician, to diffinguish with care those cases, in which imminent danger may be averted, and health restored by the use of it. I am of opinion, that there are two cases, and only two, in which venefection is likely to be attended with real advantage; 1st, When it is required to prevent the fluids gaining access to the parts more essential to life; and, 2dly, Where means must be speedily used, to counteract a threatened instammation in the intestines. But, even in these two cases, the intelligent physician is at no loss for other remedies, which may be frequently administered with a greater probability of fuccess. In the treatment of every disorder, it is necessary to fingle out that remedy, which is found most suitable to the stage of the complaint. And here we have no occasion to start the question, Whether the method and the means, by which the disease is checked and health restored, are, in the end, best calculated to prolong the life of the patient? Physicians professionally look upon every disease as an evil, which cannot be too speedily removed; and it would be to hazard the recovery of their patients, in many cases, were they to waste time in reflecting upon the confequences of the remedy with respect to its influence on the duration of life. Hence the art of prolonging life, strictly speaking, is not a distinct branch of medicine, but rather forms a separate art, and as such is the common property of all: it should therefore constitute a part of the education and studies of every rational individual, whatever be his other engagements and occupations. The abfurd notion, that blood-letting is useful and necessary to the prolongation of human life, is still pretty generally received among the common people of all countries. Neither the good nor the bad days, fuperstitiously marked in the almanacks for amusing the vulgar, can palliate or justify the mischiefs, with which this dangerous error is pregnant. Bleeding can be of service only, when it is performed at a proper time; and to express my opinion of it, in a few words,

it is always noxious to the healthy.

The blood contains and affords to the bones, ligaments, tendons, membranes, mufcles, nerves, veffels, in fhort, to the whole organized body, all the parts, which form the bones, ligaments, tendons, &c. Each of these parts is evolved from the blood, and adapted to its proper place, in fo artificial a manner, that the human mind is totally at a loss to comprehend, how this operation is performed; neither have the refearches of the most acute and attentive observers been able to account for it. And as the blood ferves to replenish the diminution, and to make up the losses, which those parts occasionally sustain, it may be considered as the original source of our whole organization. By its stimulating powers it also causes the heart and the arteries to contract; and by that means preferves the circulating motion, by which it is propelled through all the parts of the body, for the purposes designed by nature.

Now, it requires little reflection to perceive, that he who wastes this vital fluid, thereby obstructs, and, as it were, cuts off the sources of his support and regeneration. And though it be true, that the blood evacuated by periodical bleedings is soon re-produced by the activity of the vital powers, yet this restora-

tion is not effected without confiderable efforts, and at the expense of the whole machine. As this exertion, therefore, is a great pressure upon the vital powers, it must of course be attended with a proportionate degree of their consumption. It is too well known, that the corrupted part of the blood cannot be separated from the mass, so that the found and uncorrupted particles alone may remain behind. If the quality of the blood ever become vitiated and diseased; if it be too thick and viscous, or too acrid, and dissolved, the whole mass participates in the infectious taint; neither is it in the power of art, to contrive any method, by which the corrupted part may be kept asunder, from that which is in a found state. It would be equally unreasonable to expect, that a spoiled cask of wine could be cured of its tartness, by drawing or tapping the acid and corrupted portion from the top, and leaving the fweet and wholesome part behind. Lastly, experience has shewn in numberless instances, collected from different observations, that perfons accustomed to frequent blood-letting are not only rendered more delicate in their conftitutions, and thereby more subject to discases, but also that they die, for the most part, at an earlier age than others; and although cases have occurred of some persons, who, having been bled twice or four times a year, have nevertheless arrived at a considerable age, they can only prove, that venefection was to them a proper medical remedy, perhaps adapted to their peculiar habit of body; or that the activity of their vital powers, their mode of life, and other favourable circumstances, internal and external, may have been sufficient to counterbalance the dangerous consequences, resulting from the frequent loss of this essential sluid.

On the Doctrine of Transfusion.

Ar a time, when the shortness of life was imputed to a distempered state of the blood; when all difeases were ascribed to this cause, without attending to the whole of what relates to the moral and physical nature of man, a conclusion was easily formed, that a radical removal of the corrupted blood, and a complete renovation of the entire mass, by substitution, was both practicable and effectual. The speculative mind of man was not at a loss to devise expedients, or rather attempts, for effecting this defirable purpose; and this undoubtedly was one of the boldest, most extraordinary, and most ingenious attempts ever made to lengthen the period of human life. I allude here to the famous scheme of transfusion, or of introducing the blood of one animal body into that of another; a curious discovcry, attributed to Andreas Libavius, Profellor of Medicine and Chemistry in the University of Halle, who, in the year 1615, publicly recommended experimental essays to ascertain the fact. Libavius was an honest and spirited opposer of the Theosophic System, founded by the bombastic Paracelfus, and supported by a numerous tribe of credulous and frantic followers. Although Lihavius was not totally exempt from the fashionable follies of that age, fince he believed in the transmutation of metals, and suggested to his pupils the wonderful powers of potable gold; yet he diftinguished rational Alchemy from the fanatical systems then in vogue, and zealously defended the former against the disciples of Galen, as well as those of Paracelsus. He made a number of important difcoveries in Chemistry, and was unquestionably the first professor in Germany, who read Chemical Lectures, upon pure principles of affinity, unconnected with the extravagant notions of the Theofophists.*

As this remarkable feet was founded upon the doctrines of Paracellus, during the latter part of the fixteenth and the beginning of the feventeenth centuries; and as the fociety known by the name of Rofecrucians, or Rofencrucians, has not been without its followers and propagators, in different fliapes, even to the prefent time, I shall here prefent the reader with a concife account of the origin and ten-

ets of that fanatical fect.

We find this order first publicly announced to the world, in a book published in the German language, at Regensburg, in the year 1614, with the following title : " The Univerfal and General Reformation of the World, together with an Account of the famous Fraternity of the R f nerucians." In the work is an intimation, that the members of the fociety had been fecretly at work, for a century preceding, and that they had come to the knowledge of many great and important fecrets, which, if communicated to the world, would promote the happinels of man. An adventurer of the name of CHRISTIAN ROSENKREUZ is faid to have founded this order, in the fourteenth century, after being previously initiated into the sublime wisdom of the East, during his travels in Egypt and Fez. According to what we can learn from this work, the intention of the founder, and the final aim of the fociety, appear to have been to accumulate wealth and riches, by means of fecrete known only to the members; and by a proper distribution of these treasures among princes and potenter, to promote the grand scheme of the society, by producing "a general revolution of all things." In their "Confession of Faith" are

The first experiments relative to the transfusion of the blood, appear to have been made, and that with great propriety, on the lower animals. The blood of the young, healthy, and vigorous, was transfuled into the old and infirm, by means of a delicate tube, placed in a vein opened for that purpose. The effect of this operation was furprifing and important: the aged and decrepit animals were foon obferved to become more lively, and to move

many bold and fingular dogmas; among others, that the end of the world is at hand; that a general reformation of men and manners will speedily take place; that the wicked shall be expelled or subdued, the Jews converted, and the doctrine of Christ propagated over the whole earth. The Rosenerucians not only believed that these events must happen; but they also endeavoured to accelerate the same by their exertions. To their saithful votaries and sollowers they promifed abundance of celeftial wifdom, unspeakable riches, exemption from difease, an immortal state of ever-blooming youth, and, above all, the Philosopher's Stone. Learning and culture of the mind were, by this order, confidered as fuperfluous, and despifed. They found all knowledge contained in the Bible : this, however, has been supposed rather a pretext to obviate a charge, which has been brought against them, of not believing in the Christian religion. The truth is, they confider themselves as superior to Divine Revelation, and believe every useful acquisition, every virtue, to be derived from the influence of the Deity on the foul of man. In this, as well as many other respects, they appear to be followers of Paracelfus, whom they profess to revere as a messenger of the Divinity. Like him, they pretend to cure all difeases, through Faith and the power of imagination ;-to heal the most mortal disorders by a touch, or even by simply looking at the patient. The Universal Remedy was likewise a grand fecret of the order, the difeovery of which was promifed to all its faithful members.

I think it unnecessary to enumerate any more of such impious fancies, if the founder of this still lurking fect, now partly revived, had not afferted with aftonishing effrontery, that human life was capable of prolongation, like a fire kept up by combustible matter, and that he was in the poffession of a secret, which could verify his affertion. It is evident, however, from the testimony of the above mentioned Libavius, a man of unquestionable veracity, that this doughty champion in Medical Chemistry, or rather Alchemy, Paracelfus, notwithstanding his vaunting assurances, died at Salzburg in Germany, in the Hospital of St. Stephen's, in 1541; and that his death was principally brought on by the irregular and diffolute mode of life, which

he had for a long time purfued.

with greater case and rapidity. By the indefatigable exertions of Lower, in England, of DENIS, in France, and of Moritz Hoffman, and others, in Germany, this artificial mode of renovating the life and spirits was successfully followed up, and even brought to some degree of perfection. The vein usually opened in the arm of a patient was reforted to for the purpose of transfusion; into this a small tube was placed in a perpendicular direction; the same vein was then opened in a healthy individual, but more frequently in an animal, into which another tube was forced in a reclining direction; both the finall tubes were then flided into one another; and in that pofition the delicate act of transfusion was fafely performed. When the operation was completed, the vein was tied up in the same manner as in blood-letting. Sometimes a quantity of blood was discharged from the patient, previous to the experiment taking place. As few persons however were to be found, who would agree to part with their blood to others, recourse was generally had to animals, and most frequently to the calf, the lamb, and the stag. These being laid upon a table, and tied fo as to be unable to move, the operation was performed in the manner before defcribed.

In some instances, the good effects of these experiments were evident and promising, while they excited the greatest hopes of the suture improvement and progress of this new art. But the increasing abuses, to which it led bold and inexpert practitioners, together

with the great number of cases, wherein it proved unsuccessful, induced the different governments of Europe to put an entire stop to the practice, by the strictest prohibitions. And, indeed, fo long as the constitutions of men differ from each other materially as they now do, this is, and ever will be, a hazardous, if not a desperate remedy. The blood of every individual is fui generis, or of a peculiar nature, and fuits or accords, as it were, with that body only, to which it belongs, and in which it is generated. Hence our hopes of prolonging human life, by artificial evacuations and injections, must necessarily be dis-

appointed.

We are not however to suppose, that these and fimilar purfuits, during the times of which we treat as well as those which succeeded, were folely or chiefly followed by mere adventurers and fanatics. No; the greatest wits and geniuses of those times, together with the most learned and eminent men, deemed them objects worthy of their fedulous attention. LORD BACON, that fagacious explorer of the arcana of Nature, that luminary of science and talents, represents life as a flame, which is continually wasted by the surrounding atmosphere, and afferts that all the fluids of the body may from time to time be renovated, and require fuch renovation. The remedies, which he prefers and prefcribes, are conformable to this hypothesis. To prevent the external confumption produced by the circumambient air, he recommends the bath, and, after quitting it, friction with oils and falves, with a view

to fortify the pores, and exclude the influence of the external air. As means to counteract the internal waste of the body, he inculcates the propriety of a cooling, moderate diet, and, above all, extols the narcotic or foporific remedies, as the true balm of life, and the best adapted to attain the defired effect. Tranquility of mind, and a cooling diet, may no doubt be very necessary in some cases, where there is too great an irritability of temperament, and where the circulation of the blood is too rapid. But to a phlegmatic habit, they will rather be injurious than ferviceable. Narcotic remedies, too, are but ill gualified to cool and to moderate the body, fince they never fail to act as a certain stimulus, are attended with heat and relaxation, and therefore must accelerate the confumption of the vital powers: that fleep, also, which is artificial, and which they have a tendency to procure, cannot upon the whole be falutary. It is no less evident, that the vital power supplied by heat or caloric (which is principally evolved from the air,* and introduced into the body by means of respiration) must be much less considerable during sleep, than while we are awake.

For improving the fluids of the aged, and renovating the dry and corrupted part of them, Lord Bacon thinks nothing can be put in competition with powerful laxatives, and

We shall have occasion to institute a particular inquiry into the properties of air, in the next Chapter, from which it will appear, that one species of air is more noxious to the vital power than another, and that there is a greater consumption of it in one, than in the other.

advises the use of a full course of them, every two or three years at least. These remedies are, in his opinion, the best qualified to evacuate vitiated humours, and afterwards to produce, in lieu of them, milder and more heal-thy juices. The exhausted, and, as it were, thirsty vessels may be replenished and strengthened, according to his ideas, by a refreshing

and nourishing diet.

However plaufible this theory may appear, the execution of it is impracticable, and the basis on which it rests, merely conjectural. If it were peffible to withdraw the corrupted part of the fluids from the body, by means of evacuants, and at the fame time to remove the causes, which produce this tendency to corruption, then the doctrine laid down by Lord Bacon would deferve every praise, and the most minute attention to its merits. But it ought to be observed, that the activity and energy of the whole organized fystem is indifpenfably necessary in the process of separating the noxious or useless particles. As, therefore, laxatives remove only the more watery fluids; as they have a bad effect on the stomach and intestines, by rendering them too irritable, and confequently less tonic or vigorous; as the bile, a fluid so essential to the concoction of food and affimilation of alimentary matter, is thereby uselessly wasted; as the balance between the folid and fluid parts of the body is in this manner destroyed; and as, upon the whole, the vital powers must sustain a considerable degree of diminution in affording supplies, to repair what is lost;—the precarious nature of cvacuants, as the means of prolonging human life, appears too evident to require further illustration.

It is not, therefore, in fuch remedies as these, which can only be employed with safety, where a judicious attention is paid to the case and circumstances of the patient, that we ought to conside, as the most proper to prolong the period of our existence: we must search for means less dangerous and more effectual.

There is a pretty numerous class of men, who profess to calculate the length of their lives, not so much by the number of years or days they have lived, as by the use they have made of them, or, to speak more plainly, by the quantum of fenfual pleafure they have enjoyed. Persons of this cast, though fully senfible of the unavoidable confequences, are not averse to what is called fast living. Accustomed to reckon only upon the enjoyments of life, they wish to attain these in a shorter period of time, and in more rapid fuccession, rather than flowly and by degrees; especially as the duration of our life ever remains uncertain. Men of this fanguine character may be aptly compared to a plant forced in a hothoute, which will indeed grow up fuddenly, but, if contrasted with a plant of slower growth, or any kind of fruit which gradually ripens to maturity, will be found much degenerated, neither possessing the solidity and strength of stalk, nor the astringent, aromatic, and other properties, in that vigour and perfection, which we find in vegetables

raised in the open air. Many similar hothouse plants are discoverable among men, in the different flages of fociety. In childhood, they display the premature acquirements of youth; in youth, they show the sense ambition, and other qualifications of manhand; and before they have well passed through the prime of virility, they are either fratched away by untimely death, or their faculties

become blunted and impaired.

It is the unalterable plan of Nature, to proceed, in every one of her operations, by degrees; all outrage and extravagance militate against her established laws. The true enjoyment of life does not confift in the hafty purfuit of pleafure, nor in the intemperate indulgence of our fenfual appetites. The epicure is foon laid up by dangerous furfeit, refulting from indulgence in a variety of highly-flavoured dishes, and is obliged to spend that time in reluctant confinement, which he proposed to devote to his bottle, to his debauchery, or to some scene of gaiety; he is compelled to lead as it were a vegetable life, scarcely pitied by his friends, and, in the fullest sense of the word, to exist rather than

In one respect, we have little occasion to extol our own enlightened age, at the expense of those which are so frequently and justly termed dark: I allude to the bold and artful defigns of imposture, and particularly medical imposture. We daily see illiterate and audacious empirics sport with the lives of a credulous public, that feem obstinately resolved to shut their ears against all the suggestions

of reason and experience.

The host of empirics and mountebanks, to be found in our great cities, and the tinctures, essences, and balms of life, so much in vogue with even the polished classes; the celestial beds, the enchanting magnetic powers, lately introduced into this country by Messer and his numerous disciples; the prevailing indifference to all dietetic precepts; the singular imposition practised on many females, in persuading them to wear the inert acromatic belts (which shall be further noticed in the eighth chapter); the strange infatuation of the opulent to pay five guineas for a pair of metallic tractors,* not worth a sixpence; the tables for

* The Monthly Reviewers, in examining Mr. Perkins's pamphlet on that tubject, after having informed the reader that a Dr. Willard, an American practitioner, the author himself, and four other persons, had purposely burnt themselves with a red-hot piece of iron, so that blisters were raised, in order to experience the anodyne effects of the tractors, and that all these living witnesses obtained relief in a sew

minutes, proceed in the following words:

"This zeal for knowledge is truly edifying, especially as the tracters are generously presented to the public at only five guineas a pair; and it is clear that one pair would suffice to cure all the burns and sealeds of a large parish. Why are not such luculent experiments repeated here? If Mr. P. or any admirer of the discovery, would submit to have a red-hot poker run into some part of his body not necessary to life (into that part where bonour's lodged, according to Butler, for example,) in any public cosse-house within the bills of mortality, and would afterwards heal the wound in presence of the company, in ten minutes, or in half as many hours, by means of the tractors, the most stony-hearted insidel could not resist such a demonstration. Why trisse with internal inflammations, when such an outward and visible sign might be afforded?

"Mr Perkins has taken some pains, in the first part of his pamphlet, to shew that the operation of his rods is not derived from animal magnetism. In our opinion, this is an unnecessary piece of trouble in England, where there is a constant succession of similar pretensions. The virgila divinatoria, and the baquette of the juggler, are the genuine prototypes of this mystery. We were indeed rejoiced on Dr. Perkins's account, to find that the Connecticut Society

blood-letting, and other abfurdities still inserted in popular almanacks, fufficiently evince, that this is far from being the "Age of Reafon;" that the Temple of Superstition is yet thronged with numberless votaries; that human reason is still a slave to the most tyrannical prejudices; and that there is no readier way to excite general attention and admiration, than to affect the mysterious and the marvellous.

The visionary system of JACOB BÖHMEN has lately been revived in some parts of Germany. The ghosts and apparitions, which have disappeared from the times of Thomasius and Swedenborg, have again, it feems, left their graves, to the great terror of fanaticifin. New and unheard-of prophets announce their Divine mission, and, what is worfe, find implicit believers! The inventors of fecret medicines are rewarded by patents, and obtain no fmall celebrity; while fome of the more conscientious, but less fortunate adepts, endeavour to amuse the public with popular systems of medicine! These, however,

had only denounced him as a M fmeriff; we trembled lest he should have been put into the inquisitorial hands of the old women, as a white witch.

[&]quot; To trace the relations and dependencies of projects fimilar to that of Dr. Perkins, would now be a work of more labour than utility. The fund of public credulity is an inexhaustible resource for these who can resolve to key contributions on it. In vain is the ipirit of quackery exorcifed in one form; it rifes again immediately, with twenty ghaftly murders on its head, to puft us from our flow's. We, who have contemplated the progress of real knowledge, during a long coarse of years, have seen many bubbles like this glitter for a moment, and then disappear for ever. People may talk of Mignerism or Perkinism; but we consider all such varieties as belonging to the old and extensive class, Charlat nifm." - Wonthly Review, April 1799, p. 463 and 464.

are harmless, in comparison with the daring experiments, of which I shall briefly sketch

the history.

One of the most dazzling and successful Inventors in modern times was Messmer, who began his career of Medical Knight-errantry at Vienna. His house was the mirror of high life; the rendezvous of the gay, the young, the opulent, enlivened and entertained with continual concerts, routs, and illuminations. At a great expense he imported into Germany the first Harmonica from this country; he established cabinets of natural curiosities, and laboured constantly and secretly in his chemical laboratory; so that he acquired the reputation of being a great Alchemist, a philosopher studiously employed in the most useful

and important refearches.

In 1766 he first publicly announced the object and nature of his fecret labours :- all his discoveries centered in the magnet-which, according to his hypothesis, was the greatest and fafest remedy hitherto proposed against all diseases incident to the human body. This declaration of Messimer excited very general attention; the more fo, as about the fame time he established an hospital in his own house, into which he admitted a number of patients gratis. Such disinterestedness procured, as might be expected, no small addition to his fame. He was, besides, fortunate in gaining over many celebrated physicians to espouse his opinions, who lavished the greatest encomiums on his new art, and were instrumental in communicating to the public a

number of successful experiments. This sceins to have jurpassed the expectations of Messiner, and induced him to extend his original plan farther than it is likely he first intended. We find him toon afterwards affuming a more dognatical and mysterious air, when, for the purpose of shining exclusively, he appeared in the character of a Mazician—his pride and egotism would brook neither equal nor com-

petitor.

The common Loadstone, or Mineral Mignet, which is fo well known, did not appear to him fufficiently important and mysterious: he contrived an unufual and unknown one, to the effect of which he gave the name of 'Animal Magnetism.' After this he proceeded to a still bolder assumption, every where giving it out, that the inconceivable powers of this fubtle fluid were centered in his own person. Now the Mono-drama began; and Messiner, at once the hero and chorus of the piece, performed his part in a masterly manner. He placed the most nervous, hysteric, and hypochondriac patients opposite to him; and by the fole act of stretching forth his singer, made them feel the most violent shocks. The effects of this wonderful power excited univertal aftonishment; its activity and penetrability being confirmed by unquestionable tellimonies, from which it appeared, that blows, refembling those given by a blunt iron, could be imparted by the operator, while he himself was separated by two doors, nay even by thick walls. The very looks of this Prince of Juggiers had the power to excite painful cramps and twitches.

This wonderful tide of fuccess easily instigated his indefatigable genius to bolder attempts, especially as he had no severe criticisms to apprehend from the supersitious multitude. He roundly afferted things, of which he never offered the least shadow of proof; and for the truth of which he had no other pledge to offer, but his own high reputation. At one time he could communicate his magnetic power to paper, wool, silk, bread, leather, stones, water, &c.—at another he pronounced, that certain individuals possessed a greater degree of susceptibility for this power than others.

It must be owned, however, to the honour of his cotemporaries, that many of them made it their business to encounter his extravagant pretensions, and to refute his dogmatical assertions with the most convincing arguments. Yet he long enjoyed the triumph of being supported by blind followers; and their too great number completely overpow-

ered the fulfrages of reafon.

Messer perceived at length, that he should never be able to reach, in his native country, the point which he had fixed upon, as the term of his magnetical career. The Germans began to discredit his pompous claims; but it was only after repeated failures in some important promised cures, that he found himself under the necessity of seeking protection in Paris. There he met with a most flattering reception, being carested, and in a manner adored, by a nation which has ever been extravagantly fond of every thing new, whim-

fical, and mysterious. Messmer well knew how to turn this national propenfity to his own advantage. He addressed himself particularly to the weak; to fuch as wished to be confidered men of profound knowledge, but who, when they are compelled to be filent from real ignorance, take refuge under the impenetrable shield of mystery. The fashionable levity, the irrefistible curiosity, and the peculiar turn of the Parifians, ever folicitous to have fomething interesting for conversation, to keep their active imagination in play, were exactly fuited to the genius and talents of the inventor of Animal Magnetism. We nced not wonder, therefore, if he availed himfelf of their moral and physical character, to infure eafy entrance to his doctrines, and fuccess to his pretended experiments: in fact, he found friends and admirers, wherever he made his appearance.*

^{*} His first advertisement was couched in the following high-founding terms: "Behold a difcovery which promifes unfpeakable advan-tages to the human race, and immortal fame to its author! Behold the dawn of an univerfal revolution! A new race of men shall arise, shall overspread the earth, to embellish it with their virtues, and render it fertile by their industry. Neither vice, nor ignorance, shall stop their active career; they will know our calamities only from the records of history. The prolonged duration of their life will enable them to plan and accomplish the most laudable undertakings. The tranquil, the innocent gratifications of that primeval age will be restored, wherein man laboured without toil, lived without fortow, and expired without a groan! Mothers will no longer be fubject to pain and danger during their pregnancy and child-birth; their progeny will be more robust and brave; education's now rugged and difficult path will be rendered fmooth and easy; and hered tary complaints and difeafes will be for ever banished from the future aufpicious race. Parents will impart to them the activity, energy, and graceful limbs and demeanour of the primitive world. Fathers, rejoicing to fee their posterity of the fourth and fifth generations, will only drop, like fruit fully ripe, at the extreme point of age! Animals and plants, no less susceptible than man of the magnetic power,

What splendid promises! what rich profpects! Mesliner, the greatest of philosophers, the most virtuous of men, the physici in and saviour of mankind, charitably opens his arms to all his follow-mortals, who fland in need of comfort and affidance. No wonder that the cause of Magnetifin, under such a zerlous apostle, rapidly gained ground, and obtained every day large additions to the number of its converts. To the gay, the nervous, and the difficated of all ranks and age, it held but the most flattering promises. Men of the first respectability interested themfelves in behalf of this new philosophy; they anticipated, in idea, the more happy and more vigorous race to proceed, as it were by enchantment, from the wonderful impulfive powers of Animal Magnetism. Nay, even the French Government was so far seduced by these slattering appearances, as to offer the Germin Alventurer thirty thousand livres for the communication of his fecret art. He appears, however, to have understood his own interest better than thus to dispose of his hypothetical property, which upon a more accurate investigation might be excepted against, as confishing of unfair articles of purchase. He consequently returned the following answer to the credulous French Ministers:—

will be exempt from the reproach of barrenness and the ravages of a temper. The flocks in the fields, and the plants in the gardens, will be more vigorous and nourishing, and the trees will bear more beautiful and blue us fruits. The human mind, once endowed with this elamentary power, will probably rife to ftill more fublime and a comfining effects of nature:—Who indeed is able to pronounce, with certain 1, how far this falutary influence may extend?

"That Dr. M. confidered his art of too great importance, and the abuses it might lead to, too dangerous for him at present to make it public; that he must therefore reserve to himself the time of its publication, and mode of introducing it to general use and observation; that he would first take proper measures to initiate or prepare the minds of men, by exciting in them a susceptibility of this great power; and that he would then undertake to communicate his secret gradually, which he meant to do without hope of reward."

Messmer, too politic to part with his secret for so small a premium, had a better prospect in view; and his apparent difinterestedness and hesitation served only to sound an overcurious public; to allure more victims to his delusive practices; and to retain them more firmly in their implicit belief. Soon after this, we find Meffmer eafily prevailed upon to institute a private society, into which none were admitted, but fuch as bound themselves by a vow to perpetual fecrecy. These pupils he agreed to instruct in his important mysteries, on condition of each paying him a fee of one hundred louis. In the course of six months, having had not fewer than three hundred fuch pupils, he realized a fortune of thirty thousand louis. It appears, however, that his disciples did not long adhere to their engagement: we find them separating gradually from their professor, and establishing schools for the propagation of his system, with a view, no doubt, to reimburse themselves for their expenses in the acquisition of the magnetising art. But few of them having clearly understood the enigmatic terms and mysterious doctrines of their foreign master, every new adept exerted himself to excel his fellow-labourers, in additional explanations and inventions: others, who did not possess, or could not spare the sum of one hundred louis, were industriously employed in attempts to discover the fecret by their own ingenuity; and thus arose a great variety of magnetical sects. At length, however, Messmer's authority became suspected; his pecuniary acquisitions were now notorious, and our humane and difinterested philosopher was affailed with critical and fatirical animadversions from every quarter. The futility of his process for medical purposes, as well as the bad confequences it might produce in a moral point of view, foon became topics of common conversation, and at length excited even the apprehensions of Government. One dangerous effect of the magnetic affociations was, that young voluptuaries began to employ this art, to promote their libidinous and destructive designs.

As foon as matters had taken this ferious turn, the French Government, much to its credit, deputed four respectable and unprejudiced men, to whom were afterwards added four others of great learning and abilities, to inquire into, and appreciate the merits of the newdiscovery of animal magnetism. These philosophers, among whom we find the illustrious names of Franklin and Lavoisier, recognized indeed very surprising and unexpected phe-

nomena in the physical state of magnetised individuals; but they gave it as their opinion, that the power of imagination, and not animal magnetifin, had produced these effects. Sensible of the superior influence, which the imagination can exert on the human body, when it is effectually wrought upon, they perceived, after a number of experiments and facts frequently repeated, that Contact or Touch, Imagination, Imitation, and excited Senfibility, were the real and fole causes of those phenomena, which had so much confounded the illiterate, the credulous, and the enthusiaffic; that this boafled magnetic element had no real existence in nature; consequently that Messmer himself was either an arrant Impostor, or a deceived Fanatic.

In the mean time, this magnetifing bufiness had made no finall progress in Germany; a number of periodical and other publications vindicated its claims to public favour and attention; and fome literary men, who had rendered themselves justly celebrated by their former writings, now appeared as bold and eager champions in support of this mystical medley. The ingenious LAVATER undertook long journies for the propagation of Magnetifm and Somnabulifin*—and what manipulations and other abfurdities were not practifed on hysterical young ladies in the city of Bre-

^{*} Somnabulifm is the art of exciting fleep in persons under the influence of Animal Magnetism, with a view to obtain, or rather extort, during this art.ficial fleep, their verbal declarations and directions for curing the discases of body and mind. Such was the rage for propagating this mystical nonsense, that even the pulpit was occalienally reforted to, in order to make-not fair penitents, but feir profelytes to the fystem.

men? It is further worthy of notice, that an eminent physician of that place, in a recent publication, does not fcruple to rank magnetism among medical remedies! Yet it must be confessed, that the great body of the learned, throughout Germany, have endeavoured, by strong and impartial criticism, to oppose and refute Animal Magnetism, considered as a medical system. And how should it be otherwife, fince it is highly ridiculous to imagine, that violent agitations, spasms, convulsions, &c. which are obviously symptoms of a diseased state, and which must increase rather than diminish the disposition for nervous discases, can be the means of improving the constitution, and ultimately prolonging human life? Every attentive person must have obferved, that too frequent intercourse between nervous and hypochondriac patients is infectious; and, if this be the case, public assemblies for exhibiting persons magnetifed can neither be fafe nor proper. It is no small proof of the good fense of the people of this country, that the professors of this fanatical art could not long maintain their ground; that they were foon exposed to public ridicule on the stage; and that the few who are still left, are banished to dark alleys and obscure cellars of the metropolis.

Some other plans for the prolongation of life deferve to be mentioned, though fcarcely

less absurd than the preceding.

The French Count of ST. GERMAIN made large fums, by vending an artificial Tea, chiefly composed of Yellow-Saunders, Senna-leaves,

and Fennel-feed; puffing it off by the specious name of Tea for prolonging life. It was once swallowed with great avidity all over the continent; but its celebrity was short-lived, and its promised beneficial effects were never realized.

Another impudent adventurer, the Chevalier D'AILHOUD, presented the world with a Powder, which met with fo large and rapid a fale, that he was very foon enabled to purchase a whole Comté. Instead, however, of adding to the means of fecuring health and long life, this famous powder is well known to produce constant indisposition, and at length to cause a most miserable death; being compounded of certain drugs, which are clearly of a poisonous nature, although flow in their operation. And yet there are on the continent, even to this day, feveral respectable families, who persist in the use of this deleterious powder, from an ill-judged partiality for its inventor.

Count Cagliostro, that luminary of modern Impostors and Debauchees, prepared a very common stomachic Elixir, which he sold at an enormous price, by the name of "Balm of Life;" pretending, with unparalleled assurance, that by the use of this medicine he had attained an age exceeding 200 years, and that he was thereby rendered invulnerable to all attempts by poison. These bold affertions could not fail to excite very general attention. During his residence at Strasburg, while he was descanting, in a large and respectable company, on the virtues of his an-

tidote, his pride was mortified by a severe check. A Physician who was present, and had taken part in the conversation, quitting the room privately, went to an Apothecary's shop, where having ordered two pills to be made of an equal fize, and agreeably to his directions, he fuddenly appeared again before Cagliostro, and addressed him as follows: "Here, my worthy Count, are two pills; the one contains a mortal poison, the other is perfectly innocent; choose one of these, and Swallow it, and I engage to take that which you leave. This will be confidered as a decifive proof of your medical skill, and enable the public to afcertain the efficacy of your extolled Elixir." Cagliostro took the alarm, made a number of apologies, but could not be prevailed upon to touch the pills. His opponent swallowed both immediately, and' proved by his Apothecary, that they might be taken with the most perfect safety, being only made of common bread. Notwithstanding the shame of this detection, Cagliostro still retained numerous advocates and partifans, by circulating eccentric notions, and concealing his real character by a variety of tricks.

The inspired Father Gassner, of Bavaria, ascribed all diseases, lameness, palsy, &c. to diabolical agency, contending from the history of Job, Saul, &c. recorded in Sacred Writ, that Satan, as the grand enemy of mankind, has a power to embitter and shorten our lives by diseases. Vast numbers of credulous people slocked to this fanatic, for the purpose of obtaining relief. Whole cargoes

of patients, afflicted with nervous and hypochondriac complaints, befieged him as it were in his quarters every day; all stimulated and heated with a wild imagination, all eager to view and to acknowledge the works of Satan! Men of literary character, even the Natural Philosophers of Bavaria, were hurried away by the stream, and completely blinded by this sanctimonious Impostor.

It is no less aftonishing than true, that in the year 1794, a Count Thun, at Leipzig, pretended to perform miraculous cures on gouty, hypochondriac, and hysterical patients, merely by the imposition of his facred hands. He could not, however, raise many disciples in a place, that abounds with Sceptics and

Unbelievers.

It would be trespassing too much on the limits I have proposed to myself, were I to enumerate the various remedies advertised in the daily papers, both British and foreign, under the sictitious and fraudulent pretence of prolonging life. I shall therefore only remark, in general, that all these celebrated specifics are obviously composed upon wrong principles; inasmuch as their inventors proceed on the hypothetical idea, that disease is the only cause of shortening life; and, being thus mistaken, it is no wonder that they carry the strengthening or bracing system to an extravagant degree.

The highest point of bodily vigour and health may of itself contribute to shorten life; although no external causes should appear as co-operating to hasten the consump-

tive process. Nay, the very remedies we use, and the regimen we attend to, for the prevention or cure of diseases, may be of such a nature as to promote that consumption.

Absurdity of Specific Remedies.

FROM the doctrines now laid before the reader, I hope I shall not be thought unreationable, in drawing this conclusion:—That the plans for prolonging human life are generally erroneous and injudicious; that all artificial means have rather a tendency to shorten than to prolong it; and that we can never safely expect the accomplishment of this great object, unless we pursue methods more consonant to nature, more verified by experience.

The truth of this inference will be more evident, when we come to inquire into the conditions, which are effentially requifite to the

attainment of a long life.

The first of these is a certain bodily and mental disposition to longevity, not easily defined, yet sufficiently known and understood. In whatever this disposition may consist, it is a matter of astonishment, and inexplicable by the laws of animal economy, that many individuals, frequently under the most unsavourable circumstances, and in the most unwhole-some climates, have attained to a great and happy age. It may indeed be considently affirmed, that, without this principal requisite, all others

advantages are often of no avail; the most falul rious country air, a district abounding with aged inhabitants, a rigid adherence to the diet of Cornaro, a regular course of exercife and recreations, with the best art of the physician, are not alone sufficient to insure the felicitous prospect of a long and healthy life.*

Secondly: It is certain that there is, in most cases, a fort of hereditary disposition to longevity; an innate principle or quality, which, like many family diseases, is propagated from one generation to another. Perhaps nine out of ten old persons could make it appear, that their parents and ancestors also lived to a great age; a reafon which may be admitted without having recourse to any material substance, as the cause or effect of this inherent virtue.

The third requisite to longevity is a perfect birth of the child, and a proper subsequent conduct in the mother; upon which subject it is not my intention to expatiate in this place. That acute physiologist, Lord Bacon, fornewhere remarks, "that children partake more of the nature of the mother, the longer

^{*} If these rational means be unavailing to insure longevity, still more so are those miraculous remedies introduced by superstition. The ancients conceived the idea of a principle of life, which they compared to a radical fluid ;-the Alchemists expected to find this original entity in gold, by the use of which they pretended that the human body neight acquire the solidity and durability of that metal. Others traced the germ of life in bodies of confiderable duration; iu plants and animale; in the wood of the Cedar, and in the flesh of the Stag. BOERHAAVE has made a facetious remark upon the fubject : "This notion," fays he, " is just as ridiculous as that of the man, who, in order to prepare himself for the business of a running footman, is faid to have lived for some time entirely on the flesh of hares; hoping thus to furpass all his fellows in agility."

time she has nursed them; and that those children which most resemble the mother, will be generally found to have a claim to-longevity."

Fourthly: A gradual, and not too precipitate culture of the physical and mental faculties may be properly considered as an excellent preliminary step towards prolonging life. The age of man bears a certain proportion tothe growth of his various powers; and the longer we can protract the different stages of life, the more extended will be the whole compass of our existence. As it is evidently the defign of nature, that man should live longer than most of the lower animals, he of course requires a greater space of time, to develope the faculties both of mind and body. Animals, which arrive foon at the perfection of their nature and form, live but a short time. Man requires upwards of twenty, and according to some, twenty-five years, before he attains to full maturity; and if it be a rule of nature, that animals in general live eight times the number of years, which is requisite to the attainment of their perfect growth, a strong; presumption arises, that the age of man might be extended to nearly two hundred years. In the works of the illustrious Bacon, and particularly in his "Historical View of Life and Death," are given many strong arguments to confirm this affertion. Surprifing as it may appear to some, there is a possibility at least, if not a probability, that the term of human life might be still further extended, if mankind could by any means be perfuaded to re128

turn to that primeval state of nature, from which history and tradition have furnished us with fuch aftonishing and almost incredible instances of longevity. It is not my intention here to inquire into the degree of credit. which may be due to the accounts of some extraordinary facts of individual longevity, recorded by the facred historian; as the learned vary much in their opinion, relative to the mode of computation, and whether the Solar. the Arabic, or the Lunar year, or a still shorter measure of time, is alluded to. This, at least, seems to be generally admitted, that the antediluvians enjoyed an enviable, uninterrupted state of health; that their vegetable aliment, and general mode of living, were extremely simple and no wife prejudicial; that the constitution and temperature of the globe itself must have been greatly affected and deteriorated, in consequence of the Flood, or other causes of which we are ignorant; and, lastly, that those impetuous and inordinate appetites and passions, which, like slames, may now be faid to confume the powers of life, were then either less violent, or exerted their baneful influence at a much later period of life...

Nature refents every outrage committed on her treasures, and seldom fails to punish the transgressors with lingering disease, or early dissolution. This observation may be applied to the moral as well as the physical faculties of man. It is commonly said, and not without some degree of truth, that very forward

children seldom live to any age; and that too carly an exertion of mental powers is inmost cases destructive. The same remark holds good in what relates to the body. The inhabitants of hot climates, who frequently marry at the age of ten and twelve, or twelve and sourteen, begin to be old at thirty, and rarely survive the sixtieth year. Every thing which hastens the evolution of the natural powers, every exertion of strength, disproportionate to the ability of the individual, should be carefully avoided, as of a dangerous tendency. Hence the great art of education, the great art of living, consists in following the

path of nature.

Fiftbly: We should constantly inure ourfelves to the habits of supporting and refishing the various impressions of external agency.-Some persons who have paid a very rigid attention to diet, have notwithstanding been unable to reach even a middling age; while others, who have been addicted to the most irregular and extravagant courses, have been, observed to live to one very advanced. Hence arise contradictory maxims in dietetics, which can only be reconciled by deciding chemically between the two extremes, and afcertaining pretty nearly the absolute and relative falubrity of things. All deviations from the rules. of diet are in a certain degree hurtful; although these may, in most cases, have only a limited value. Many epicures have been known to reach their feventieth and eightieth, year, if they have once furvived a certain critical period of their lives.* As foon as the body becomes accustomed to the use of certain things, at first disagreeable and perhaps hurtful, the noxious tendency will not only be removed, but we shall find our frame hardened and strengthened by the habit of using them. Nature must stand many a shock, if she would familiarize herself to the vicislitudes of climate and opposite modes of life, but every victory the gains in these encounters, will be a means of rendering her more vigorous and unconquerable. How could the fublime mind of FREDERIC THE GREAT have remained fo long. in its earthly vehicle, if he had not improved, by constant culture and discipline, his original disposition to a long life? A thousand other men, who have endured as much exercise of body and exertion of mind in their younger years, have yet not attained to any remarkable age.—Severe and obstinate discases have also been thought, in many instances, to contribute to the prolongation of life: this is at best, however, but a doubtful point; although it cannot be denied, that many fick persons have, to all appearance, acquired additional

Experience shows, that there is a particular term of life which, if we can pass in the fullness of health and vigour, leaves the greatest probability of living to a considerable age. In the semale sex, this period generally arrives at, or before, the liftieth year; in the male, it is about the fixtieth year. Gellius, a medical author of credit, afferts, from observations founded on long experience, that the sixthird year is, to most constitutions, a critical and dangerous one.—The figyptians called this epocha Androcles, because man begins from that time to experience a rapid decay of strength and energy. Others, rather more superfittiously, maintained that, about this period, many individuals die, or at least are subject to severe attacks of disease.—The Emperor Augustus received the congratulations of his friends, on having survived this trying period.

frength and spirits, after having recovered from a distressing quartan ague, or some

threatening pulmonary diforder.

Sixtbly: We may take notice of a certain Ready and equal progress through life, as highly conducive to the great object in view, whether it flows in the manner of a gentle stream, or resembles the more active course of a rapid river. The mind, when accustomed to certain fituations and purfuits, which almost constantly affect it in an uniform manner, is most likely to preserve its reasoning powers unimpaired and ftrong. He whom neither violent joy convulses, nor deep melancholy corrodes, whose drama of life is not chequered by too fudden viciffitudes, may, with fome probability, expect a long enjoyment of that life, to which he has become fo habituated. There are many whose days quietly glide away, like those of a simple rustic, in continual fameness: fuch persons, it is observed, generally live to a great age.

Seventhly: A very necessary cause of the attainment of an advanced age, is a sound state of digestion. In very old persons, we generally find the digestive organs in excellent condition; nor is there a surer symptom of approaching dissolution, than complaints in the stomach, or frequent returns of indigestion. The Swiss are indebted, it is thought, to the vigorous tone of their digestive powers, for the long preservation of their lives, in general, and for the great number of aged persons among them. Milk and vegetable food seem remarkably well adapted to invig-

orate the stomach. To effect the same purpose, Lord Bacon advices old people to have recourse to strengthening baths, somentations, and similar external remedies, which operate upon the absorbent system. At the same time, a thin but nourishing and moderate diet should be observed, in order to spare the

organs of digettion.

Eighthly, and lastly: We may recommend equanimity, or that state of the mind, when, from the happy nature of its pursuits, it is not disquieted by too violent exertions. In the literary professions, and particularly among such individuals as are placed in easy circumstances, we discover as many instances of longevity, as in the more laborious occupations. It was remarked by the Ancients, that grammarians and rhetoricians commonly attained a great age. The mind being engaged in fcientific pursuits, and other objects in which it finds pleafure, fuch as convertation on literary and mixed topics, collecting the productions of nature, a continual feries of mental research, diversifying the pursuits or animfements, yet gradually and conflantly persevering in exertions towards the attainment of forme principal object—all supply the vital power, as it were, with materials, like the cruse of oil, which proved a never-failing support to the widow of Sarepta. On the other hand, it is a general remark, that deep thinkers, speculative philosophers, and those whose powers are continually absorbed in abstruse inquiry, foon feel the effects of age, from the great exertions of their mental powers. This mult be understood, however, with exceptions, as in the cases of SIR ISAAC NEWTON, HALLER, EULER, and the pride of his nation and age, the profound and venerable KANT, still living

at Kænigsberg.

I venture to fay thus much on the various rules and precautions requifite to attain a long and healthful life. Some of the particulars are, no doubt, found united in a certain proportion of the individuals, who arrive at a respectable age. It is commonly remarked alfo, that the inhabitants of mountainous countries, for the most part live to a greater age than those of plain and, particularly, marshy districts. This is in part true; yet we are not to confider the lofty regions in the Alps and Pyrenees as possessing these falubrious qualities; for it is only upon moderate heights, and in hilly rather than mountainous countries, that we fo frequently meet with people of an unufual age. Perfons who are conflantly travelling, are likewise said to enjoy a long and healthful life; and Lord Bacon further includes, in the lift of long livers, fuch as are of a melancholy temperament. It is a questionable point, whether the great age of many Turks is to be afcribed to the ferenity of their climate, their daily use of the bath, or their uncommon temperance in eating and drinking. For, as to their copious uie of opium, which is confidered by them almost as necessary as food, we have already shown the noxious tendency of fuch practice; opium generating, in a remarkable degree, a disposition of the fluids, in many respects resembling that of hypochondrias. There is scarcely an instance of any person, that has attained to uncommon longevity, who has not been particular in his diet and manner of living. But in this respect we cannot hope to derive advantage from excessive solicitude:—for, as when in want of sleep, the more we think of it, the more it shuns us; so those who are most anxious for longevity, are the least likely to attain it. Age is a gift, which Heaven frequently bestows upon mortals, when they are assept, or in other words, when they are fearcely sensible of it!

On the Symptoms of actual Diffolution.

THAT many unfortunate individuals are configned to the grave, before they are actually dead, is a truth too well attested to require demonstration. If this were not, or never had been the case, it could not have excited that degree of attention on the Continent, and particularly in Germany, which of late years has been bestowed on this important subject. The most respectable Physicians have proved by incontrovertible facts, that fick persons have often been hastily buried, or to speak more properly, smothered in their coffins, either from accidental miltake, or from the most detestable motives. But, as many false and scandalous reports are generally circulated, in addition to those founded on truth, we need not wonder, that this business has

not been conducted, hitherto, with that degree of calm and patient attention, to which it is justly entitled. Houses for the reception of persons apparently dead have been, at length, erected in various parts of Germany, in Berlin, Jena, Coburg, &c. This idea, at the first view of it, may to some appear whimfical; but those who know the extent of the power of vitality, and the almost infinite modifications of which that power is susceptible, will not ridicule a proposal, which originated in motives of prudence and humanity. Into these houses every inhabitant of the town, or diffrict, has a right to fend the body of a deceafed person, on paying a trisling sum per night, towards the expenses of the institution. Here the body is deposited on a couch, lightly covered, and provided with a firing fattened to the hand, which pulls a bell on the top of the house. A watchman is appointed to receive and register the bodies brought into the house, and to give the alarm, if necessary. This, to say the least of it, is no small convenience to families in a large city, crowded into narrow apartments, with a number of children, who must necessarily suffer from the pestiferous exhalations of dead bodies. But this is not the principal advantage attending fuch establishments: it is unquestionably a great satisfaction to the relatives of the deceased, to be assured that every means have been used to preserve from the most dreadful of all deaths, a friend whose memory they revere.

The cases, in which death can be clearly as-

certained, are nearly the following:

1. When putrefaction has actually taken place over the whole animal frame; as inflances are common, in which a partial mortification of an arm or a leg is by no means mortal.

2. In the nervous apoplexy of the aged, as fuch perfons generally die in confequence of flowly wasting diforders, various species of palfy, &c.

3. If the patient expires after a long flanding confumption, heelic fever, or ulcerations of the breaft and lungs, difeases now very

common.

- 4. If any of the larger blood-vessels, or other parts essential to life, have received external injury, by violent blows, bruises, or cuts, attended with great loss of blood, which could not be stopped by artificial means. If we are unable to supply the loss of this vital sluid, and to restore the organization of the parts thus destroyed; particularly if the brain, the lungs, the heart, the stomach, or any of the intestines, have suffered from a severe wound, a speedy dissolution may be considered as inevitable.
 - 5. After chronic diforders of the inteftines, obstructions of the abdominal vessel, and dropfy thence arising—ar if an incurable weakness in the breast has occasioned the organic destruction, or offssication of the pectoral vessels, there is little prospect of the recovery of such a person; as these complaints of asthmatic sufferers, in general, are not in a

just proportion to the whole state of the body; for instance, if their appetite and digestion have been unimpaired previous to their disease, or if their muscular strength has not suf-

fered from the like affections.

6. In persons of tender and debilitated nerves, who have been long subject to spasms or epileptic sits, particularly if they die in child-bed, in consequence of violent hemorrhages, or after repeated and oppressive agitations of mind;—in such cases there is no hope left, as it is too late to think of changing or improving the constitution of the nervous system. Lastly,

7. If a person gradually wastes away in a malignant nervous or putrid sever, or after long fasting from want of food. In these instances it is not in the power of the medical art to restore the shrivelled vessels to their proper tension and energy; consequently all our efforts to reanimate the body will be unavail-

ing.

There remains now to be stated also, in what cases and situations the symptoms of apparent death are less certain, so that some hope of recovery is still lest to the disconsolate friend and relative. These are principally the following: after faintings, sudden loss of blood from diseased intestines,—in certain cases of repelled morbid matter, for instance, in the small-pox, measles, poisons, and the like, which frequently produce a spurious kind of apoplexy;—after hysteric and hypochondriac spasms and colics of a transitory kind, which have not too often recurred; af-

ter mental anxiety, perturbation, terror, and other oppressive passions, where every thing depends on a speedy removal of the causes. To this lift we may likewife add the cafes of drowned, hanged, and otherwife fuffocated persons, or those who appear to be dead, in confequence of a fall from high fcaffoldings, without any external injury. In fuch accidents, an internal pressure or stoppage of the vital functions, as breathing, and circulation of the blood, often produces a state of apparent death .- Even the suppressed pulse in the arteries, imperceptible respiration, the coldness and rigidity of the limbs, the want of contractibility in the pupil of the eye, the involuntary loss of excrementitious substances,all these symptoms of approaching discolution should not discourage us from trying the proper means of recovering the patient's life. In children and young perfons, in particular, we must not too hastily decide, whether they be absolutely dead or not;—teething is frequently attended with diversified convulsive symptoms, and the tape-worm is capable of producing the most alarming effects, which the inexperienced by-standers may unwarily ascribe to very different causes. Hence every possible degree of precaution is requisite in managing the bodies of infants apparently dead, and above all things not to remove them from the warm temperature of the fick-room, before the last lingering spark of life is extinguished. Indeed, it must strike even superficial observers, that the hasty removal of a body from a warm to a colder temperature

is highly improper and dangerous. And here the excellent rules, published by the Royal Humane Society of London, for the recovery of persons apparently dead, cannot be recommended in too strong terms; although some of the more violent methods detailed in their plan, such as inflation of the bowels with the fumes of tobacco, elysters prepared of this herb, violent agitation, and too early and indiferminate application of the electric shock, might well bear a few modifications, and improvements.

Summary of Dietetics.

The knowlede of those objects which relate to the preservation of the human body, in its natural state, may be called the Dostrine of Health. Life and Health are, therefore, the proper objects of this doctrine; as the second department of Medicine solely relates to the preternatural states of man, viz. Disease and Death, and forms that branch of professional

fludy, which we call ' Pathology.'

The compass of the former science, or an investigation of the objects included in the doctrine of health, must be very extensive. It turnishes us with rules and cautions as to every thing we ought to do, or to avoid, in order to remain healthy. This useful science is properly denominated Dietetics, or a system the view of all objects relative to health in general, and to food and drink in particular.

The following Chapters will, therefore, be exclusively devoted to Dietetics. My principal object will be, to lay a folid foundation for that important science, by investigating and combating the chief prejudices, which have hitherto retarded the progress of this branch of knowledge. Hence, a System of Dietetics must not only contain all those rules, which are requisite to guide us in the preservation of health, together with such as relate to the choice of a proper mode of life, but should likewise inform us with regard to the beneficial or hurtful influence, which external ebjects produce on the health and life of man, and teach us the just application, or practical

use, of these objects.

DIETETICS include the whole of what the Ancients understood by the fingular name of the SIX Non-NATURALS; namely, Air, Aliment, Exercise and Rest, the Passions and Affections of the Mind, Wakefulness and Sleep, and Repletion and Evacuation. Although these general heads do not comprise, strictly speaking, every thing that relates to the different functions of the human body; yet they contain all fuch conditions of life, as are absolutely necessary, and the greatest part of those circumstances, which are connected with the health and well-being of the individual. In each of these particulars we are liable to commit errors, either by intemperate use, or an improper application. I propose, therefore, to lay down a System of Rules, by which we may be affifted to choose, according to particular circumstances, the best and most rational means of infuring heath, and of avoiding whatever may have a contrary tendency.

Our mode of life is no longer that netural and simple one, which prevailed in the primitive ages of mankind: in the present state of fociety fuch habits are fcarcely conceivable. Man in a ftate of nature had little occasion to attend to his health; he wanted no rules for the prefervation of it; for, as the feeds of difenfes are rarely scattered in such a state, instinct would be to him in most cases a sufficient guide. It now feems to be impossible to retun to that primeval flate, without returning, at the fame time, from our present degree of mental improvement to that of priftine barbarity. We have, to all appearance, purchased our improved state of mental culture, by facrificing to it a confiderable flure of our bodily welfare; -happy, however, we may still consider ourselves, if we have actually gained in moral and intellectual improve-

Innumerable are the causes, which have conspired to render the true knowledge of the means conducive to health, difficult in the acquisition, and uncertain in its application. The chief of these are probably the rohowing, which include most of the subordinate particulars:—the present very artificial method of living; the prodigious number of the employments of mankind; the different modes of dwelling and dressing; the endless variety of articles used as food and drink; the great diversity of national customs and manners; and the difference of climate and fituation:—

all these circumstances have greater or less influence, conjointly or feparately, not only on the passions, inclinations, and instinctive desires of individuals, but also on the general state of the health and physical welfare of a people. By the present mode of living we are exposed to diseases wholly unknown in the first ages of the world, and we fuffer from a variety of complaints, originating either in artificial habits, or the conftraint under which we labour, in consequence of blindly complying with the caprices of custom, or fashion, without perhaps apprehending any ill confequences

from fuch pernicious practices.

Many ingenious writers have lately endeavoured to point out the difadvantages arifing from causes apparently trivial. Thus the fashion of uling paint, hair-powder, and pomatum; of wearing ill-shaped shoes, laced stays, &c. have defervedly incurred fevere ridicule and pointed centure. The custom of applying lead to earthen veffels has not escaped their attention: the danger, however, refulting from the use of that substance, has been greatly exaggerated. Writers, with the best intentions, have fometimes, from an excess of zeal, descanted on the worst side of the question only, by attributing to certain things many dangerous qualities, which in fact are owing to a great diversity of circumstances.

This partial method of inquiring into the

fources of the evil, is, generally speaking, a serious error; as it not only leads to false conclusions, but also draws our attention from other pressing injuries, to which, in a more dispassionate state of mind, our care might be directed.

Many, and perhaps the greater number, of dietetic writers have fallen into another error of an equally bad tendency. They judge of every thing, according to the agreeable or difagreeable effect it produces on their own palates and conftitutions, and hence recommend their favourite articles to others; although what is falutary in particular cases, may have a pernicious tendency, if prescribed indiscriminately.

The multiplicity of our wants, all deferving attention in a Dietetic System, has also considerably multiplied the rules of health. Of all living beings, indeed, none require such rules more than those, who servilely submit to the arbitrary mandates of luxury and fashion.

Many are the open and fecret enemies to the health and prosperity of man. Even the most healthy, and those who rigidly adhere to the rules of Diet and Regimen, cannot altogether evade their attacks. Hence we should make it our study, to acquaint ourfelves minutely with every thing, fo as to be enabled to judge of its good or bad qualities. Whatever we are obliged to have more immediately about and around us, ranks in this class: the arrangement of our dwelling places, beds, clothes, furniture, &c. in the choice of which we are lefs accustomed to confult what nature requires, or to contrive what may be most likely to promote the welfare of the body, than to follow fashion; vanity, or our own habits.

Some of our organs of fense, and other saculties of the body, must unavoidably suffer from inattention to a proper mode of living in general. From the great exertions, to which we often subject them (the eyes, for instance, in reading) they are liable to a variety of accidents, and frequently become debilitated and impaired. It appears, therefore, perfectly consistent with the plan of this work, to treat of the management of the eyes, teeth, and other individual parts of the

bedy.

In a complete System of Rules for preserving the health of man, attention must be paid to the separate wants of individual constitutions; provided they be not too minute and trivial. Such a system must contain more than what relates to the first and most simple rules of living; -its precepts must not apply to the healthy alone, or those whose life is regulated by the simplicity of nature,—it should also lay down instructions, how, in all contingent circumstances, we may be secured from danger and bodily injuries. It is not, however, proposed to treat of diseases after they have taken place, if the removal of them requires any thing more than a ftrict adherence to temperance, and the other rules hid down in these Lectures.—But to prevent any misapplication of those rules which are established by the accumulated observations of age, it may not be improper to introduce here fome previous general remarks, relative to the individual use and advantage to be derived from a connected view of Dietetics.

It may be laid down as a preliminary obfervation, that the rules contained in this work are not to be confidered as strictly applicable, in every instance, to the particular situation of any individual, or as essentially necessary to the preservation of his health.— It is not so much the healthy, as the valetudinary and insirm, who stand in need of minute precepts for their conduct; and even the latter ought not to engage too solicitously in their compliance with them; since it is only a very limited number that require such accurate attention.

A vigorous and persevering method of inuring ourselves to the unavoidable difficulties and diversified accidents of life, is of greater importance to the prefervation of health, than any dietetical rules whatever. Man is capable of undergoing all the viciflitudes and inconveniences of air, weather, and climate; he can digeft any articles of food, if his ftomach has not been wantonly indulged; he can fustain the severest bodily exercise and labour, without paying too minute attention to time or regularity, when his employment or duty renders exertion necessary. But he who from his infancy has been treated with extreme tenderness, or who, after having been previoully accultomed to a hardy mode of life, is feized with the whim of bestowing too much care on his health, will fuffer from the most trivial hardships, and catch cold at every change of the air; every heavy or high-feafoned dish will be oppressive, and the smallest deviation from the rules of temperance indifpose him. Yet, by the same rules, every healthy person will learn, that the grand secret for preserving himself in that state, consists principally in the art of moderating his desires and enjoyments. We may thus arrive at the knowledge of such things, as are generally conducive to the welfare of the body; and more than this ought not to be expected. Rules of health, universally applicable to the state of every individual, are not discoverable in nature; nor can they be derived from any experimental knowledge we posses of corporeal objects.—The best general precept is, that every one study himself, and his own particular constitution; that he choose and regulate his mode of life accordingly; and that he make his own experience his guide in whatever he sinds most suitable and convenient.

CHAP. II.

Of AIR and WEATHER; their influence on the Human Body; the means of improving the former, and diminishing the pernicious effects of the latter.

Of Air in general.

S foon as an infant enters into the world, the air of the atmosphere penetrates into his lungs, filled up till then with aqueous mucus, and renders them fit for the circulation of the blood, which immediately commences. From that moment the alternate extension and contraction of the breast and lungs, the infpiration and expiration of the air, or in other words, the function of respiration, becomes indispensably necessary to the preservation of animal life. While the child remained within its mother, it required no external air. As foon, however, as it has drawn breath, as foon as the lungs are opened, the act of respiration begins, is constantly renewed through life, and can never absolutely cease, but with death. - As, therefore, air is the principal medium by which animal: life is supported, it becomes highly important to acquire correct ideas of this refined. fubstance, that pervades all the parts of animate and inanimate matter, and is so effential to man, for the preservation of bath his life and health.

Air is that colourless, transparent, compressible, heavy, and elastic fluid, which every

where furrounds our globe, and which generally receives the name of Atmosphere.* This ambient matter, in its common state, is combined with a great variety of foreign ingredients. It contains water in a state of solution; by means of water it combines with salts; in many places we find it impregnated with fulphur, with putrid exhalations, and the like; nay, frequently we even meet with earthy particles sloating in this element.—When all foreign ingredients are separated from it, the subtle aërial body still remains of

[&]quot; " Our bodies are equally preffed upon by the incumbent atmosphere, and the weight they sustain is equal to a cylinder of the air, whose base is equal to the superficies of our bodies.- Every fit square of this superficies sustains a quantity of air equal to 2660lb.; fo that if the superficies of a man's body was to contain 15 square feet, which is pretty near the truth, he would fulfain a weight equal to 30, 100lb. The difference of the weight of the air, which our bodies fultain at one time more than at another, is also very great; that between the greatest and the least pressure of air upon our bodies has been proved to be equal to 3902lb. Hence it is so far from being a wonder, that we fometimes fuffer in our health by a chan e of weather, that it is the greatest miracle we do not always do so. For when we confider, that our bodies are fornetimes prefled up a by near a ton and a half weight more than at another, and that this variation is often very fudden, it is furprifing that every fuch charge should not entirely break the frame of our bodies to pieces. A d the vessels of our bodies, being to much strained by an in real d profilire, would stagnate the blood up to the very heart, and be circulation would quite ecute, if Nature had not wifely contrived, that when the refiltance to the circulating blood is greatest, the imp tus, by which the heart contracts, should be so too. For up n increase of the weight of the air, the lungs will be more forcibly expanded, and thereby the blood more intimately broken and div d d; to that it becomes fitter for the more fluid fecretions, such as that of the (supposed) nervous fluid, by which the heart will be more firoughly contracted, and the blood's motion to x ands the furface of the body being obstructed, it will pass in greater curntity to the brain, where the presture of the air is taken off by the crani m up. on which account also more spirits will be separated, and thu to heart too more enabled to carry on the circulation through all piffable canals, while fome others towards the furface are obstructed." Quincy's New Medic. Diel .- Article, Air

a compound nature, and is by no means a fimple elementary fubstance, as was formerly believed.

According to the late discoveries in chemistry, the aërial basis of the atmosphere consists of three different species of air, namely, of pure, respirable, or dephlogisticated air; of azotic, or phlogisticated air; and of fixed, aërial, or carbonic acid air.—The proportion of the first, namely, pure or vital air, consists, according to the French Chemists, who have given it the name of Oxygen, of 27 or 28 in the hundred parts; the second, viz. the Azote of the French, of 72 or 73 in the hundred; and the third, namely, the Carbonic acid air, of about one part only in the hundred.*

The accurate experiments made by the late Scheele and Bergman, in Sweden, do not much differ from those of the French Chemits, with respect to these proportions. For, according to Scheele and Bergman, the common proportion of vital air, or oxygen, in the atmosphere, is about one fourth; that of azote about five eightlis; and that of carbonic acid nearly one sixteenth; the last of which, by the French, is computed only at one hundredth part, that is, five parts in the hundred less than the Swedish philosophers maintain.

The following is a concife history of Oxygen: -In August, 1774, Dr. PRIESTLEY, and much about the fame time Mr. Scheele, in Sweden, discovered this respirable part of atmospheric air, or rather they exhibited it, for the first time, in a pure state. This elastic sub-Rince was first called depblogifticated air, agreeably to the hypothesis of phlegifton ; - afterwards it went under different names, as pure air, ure-air, vital air, until the late hypothesis of Oxygen, or the acidifying principle, has procured it the name of oxygen gas.—But still more diversified than these names, are the theories which have been proposed on the nature and properties of this species of air, during the last twenty years. With Priestley, it is the purest air freed of all phlogiston; with Scheele, it is the nitrous acid deprived of its water; according to Birgman, it is one of the unknown constituents of aitrous acid; with Fontana, it is the dephlogisticated nitrous acid; Forfler confiders it as air united with fire; Mr. Watt, of Birmingham, thinks to find in it elementary fire combined with hydrogen or inflammable gas; Achard and Gren formerly believed it to be water combined with much Caloric, or the principle of heat; but Gren

Oxygen is much better adapted to the respiration of animals, than common atmospheric air. If two animals be inclosed in vessels, one of which contains pure oxygen, and the other common atmospheric air, in proportions equal to the fize of the animals, the former in the oxygen will be found to live from fix to feven times longer, than the latter in common air. It is properly this oxygen which we inspire, and which is the grand support of animal life. Persons apparently dead, or in a state of fuffocation, have been instantly restored to life by its influence, and from the corresponding testimony of several respectable physicians, it appears to have been employed with advantage in many obstinate diseases.-The celebrated Ingenhouz therefore gave it the name of vital air. It promotes combustion in a very high degree. A candle will burn in it from fix to seven times longer than in common air, with a much greater degree of heat, and a more brilliant flame. Bodies in a glowing state, are immediately inflamed, when put into oxygen gas; and even metals, which are not very fulible, are melted in it, and converted into oxyds, or calces, with the greatest facility.

latterly maintained, in his System of Chemistry, that it is the unknown basis of vital air combined with Caloric :—if we believe Westrumb, it is elementary air in a state of combination with Caloric, but the basis of the former cannot be discovered; according to Fourcesy, it is an unknown elementary matter united with inflammable air; in the opinion of Lawissier, it contains the acidlying principle, Oxygen, and the principle of Heat, Caloric; Mr. Gascondish maintains that it is dephlogisticated water; and according to De la Metheric, it is an unknown substance combined with wa crand fire; &c. &c.

Azote, by others called phlogisticated, mephitic, corrupted, or suffocative air, is absolutely irrespirable, and not miscible with water. It arises from the change which atmospherical air undergoes in every process of combustion, putrefaction, and respiration,

whether produced by nature or art.

Azote enters into no combination with water, but may be rendered less hurtful by shaking it with that sluid: this accounts in some measure for the falubrity of the sea-air. It greatly promotes the growth of plants, and readily accumulates in apartments silled with people, or containing articles fresh-painted with oil-colours, or in which strongly fragrant slowers are kept, without having any access of fresh air. We should be extremely cautious in entering such places; as diseases of the breast and lungs are too frequently the consequences of neglect, obstinacy, or ignorance.

The Carbonic acid of the French is the fixed air of Dr. Black, and the Aërial acid of Bergman. This species of air is miscible with water; but in its pure state equally irrespirable as the Azote. It derives its origin, partly from the vinous fermentation of vegetables, and some animal substances, and partly from the mild alkaline salts and earths combined with acids. Much of this air is found in mines, where it frequently distresses the workmen by its suffocating qualities. It is also observed in most mineral waters, where a stratum of it sometimes swims upon the surface of the well. These waters, as well as fermented liquors

which contain a confiderable portion of fixed air, receive from it the well known pungency fo agreeable to the palate. Hence flat and fpoiled beer, or wine, may be corrected and reftored to its former brifkness, by the addition of fixed air evolved from chalk and vitriolic acid, or by mixing it with new beer or wine in a state of fermentation.

This species of air quickly extinguishes fire, and strongly attracts the sumes arising from candles. As it is unfit for respiration, animals cannot live in it. The warm-blooded animals die in it much sooner than any other; those of an amphibious kind somewhat later; insects are not irrecoverably killed by it; irritability is suddenly destroyed, and the heart of an animal so deprived of life, though still warm, no longer exhibits any signs of motion.

There is another species of mephitic air, which is not miscible with water, which burns with a slame, and if mixed either with atmospheric air, or oxygen gas, instantly catches fire, and is exploded: this has received the name of inslammable air,* and deserves to be

The white Dittany, (Distannus arbus, LES.) when in flower, generates fo great a quantity of inflammable air, that the atmosphere around it has been observed to catch fire. In swamps, pools, and

^{*} This air may be obtained in a great variety of ways, from all substances liable to inflammation, or containing combustible matter, by means of heat, fermentation, acids, and the like; nay, even from metals, by directing the steam of boiling water through a red-bett metallic tube.—It is the spontaneous production of rature, throughout her three kingdoms. In mines, in subterraneous caverns, and particularly in coal-pits, it is known by the name of ile k-domp. It is copiously generated in the intestines of living animals, and is frequently met with in common sewers, burying grounds, and places where dead animal bodies are exposed to putte faction.

mentioned here, although it cannot be considered as a constituent part of the atmosphere.

With respect to the specific gravity of the different airs before enumerated, it is in this place only necessary to observe, that the heaviest is the fixed air, or carbonic acid gas; next to this comes the azote and oxygen, both of which are heavier than the common air of the atmosphere; and lastly, hydrogen, or inflammable gas, which is the lightest of all; for it is even lighter than the purest atmofpheric air.

When the atmosphere is too much impregnated with any of the mephitic gafes, its influence on the human body is extremely nexious. Thus we fee many of the workmen in lead-mines dying in the prime of life, of an obstinate and incurable colic, which is attended with the most painful obstructions.-Painters, glaziers, potters, and manufacturers of glazed earthen ware, are from a fimilar cause exposed to the same dreadful disease; being obliged to make use of great quantities of lead* in different forms.

other flagnant waters, where a number of plants, particularly fage, calmus, and the like, are putrifying, we find a species of inflan-mable gas, which is known by the name of marfb-air, or more com-

ny, the ignis fatuus, or Will-o'the-Wifp.

 Whether this infidious and deleterious metal be communicated by it -- 1g its vapours through the lungs, or by abforbing them this u h the poics of the fkin, the effects of it are equally dangerous a d total. The internal use of sulphur, and both the internal and external tile of vegetable oils, or animal fats, are the only antidotes he rto differenced against this virulent bane of the manufacturer

Me it trades and occupations are subject to peculiar diseases; in I with mater als of the manufacture have a pernicious influence or lab dy, and in others the nature of the employment is hurtful, cather from requiring a federitary life, a reclined, flooring, or itandIt is almost unnecessary to mention the frequent and sudden deaths that have taken place from the explosion of inflammable air in mines, or from the opening of pits, deep wells, and other confined places. Neither is any thing so much calculated to corrupt and poison the air, to sill it with noxious vapour, and to generate diseases, as the burying-grounds established within the walls of populous cities, where human bodies are deposited, as if with an apparent design to produce an atmosphere, which is particularly fatal to the tender lungs of children, and in no small degree hurtful to adults.

As the mass of atmospheric air is incessantly corrupted by the respiration of men and animals, by the burning of so many natural and artificial sires, by the dissolution and putresaction of innumerable substances, and by various other phlogistic or desoxygenating processes, it would at length become altogether incompetent for its original designation, if Nature had not provided effectual means for its improvement and restoration. Among the most powerful of these, we may place the growth and vegetation of plants.—For this very important discovery we are indebted to Dr. Priestley, who was so fortunate as to hit upon it, after he had long employed lim-

ing posture, or from being performed in a confined air, or at a great fire, and the like. Hence millers, hair-dressers, and steve-mas m, frequently die of a consumption of the lungs, in consequence of the nature particles of dust which they are continually obliged to intele-Manufacturers of wool, and particularly hatters, are much trood with obttinate cutaneous diseases; and all those whose business is attended with grease and dust, suffer more or less from the consequences of uncleanness.

felf in fruitless attempts, to improve and reflore corrupted air, by artificial means. He found that air, rendered mortal by the breathing of animals which had expired in it, was again so completely restored by the vegetation of plants, that, after the lapse of some days, an animal could live in it with equal ease, and for the same length of time, as in a similar

quantity of common atmospheric air.

These experiments, indeed, did not succeed with fome Naturalists; and Priestly himself, upon repeating them with different plants, found the refults rather varying and doubtful: but Dr. Ingenhouz removed the greater part of these difficulties, by his book, "Experiments upon Vegetables, 8vo. London, 1779." This ingenious philosopher remarked, 1st, That most plants have the property of correcting bad air within a few hours, when they are exposed to the light of the fun; but that, on the contrary, during the night, or in the shade, they corrupt the common air of the atmosphere; -2d, That plants, from their own fubstance, afford a very pure dephlogifticated air, or Oxygen, when exposed to the rays of the fun; but a very impure air or Azote at night, or in the shade; -3d, That not all the parts of plants, but only the green stalks of leaves, particularly through the sides opposite to the soil, produce this beneficial effect; -4th, That the difengagement of pure or vital air does not commence until the fun has been some time above the horizon; that it ceases altogether with the termination of day-light; and that the disadvantage arising

from the impure exhalation of plants, during the night, is far exceeded by the great advantage they afford during the day; infomuch, that the impure air, generated by a plant dur. ing the whole night, fearcely amounts to a hundredth part of the pure vital air or Oxygen, exhaled from the fame plant in two hours of a ferene day.—Thus we discover a most firiking phenomenon in the economy of nature; fince the vegetation of plants continually counteracts the noxious effects of respiration, combustion, and putrefaction.* In this manner, the atmosphere is constantly preferved in that necessary state of purity and temperature, which is the most falutary both to animals and vegetables.

We have learnt the effects produced on the human body by the atmosphere and the changes of the weather, partly from observations made by ourselves and others, and partly from their influence on inanimate matter, by which we can judge in some measure of its analogous effects on the human frame; but we should not thence conclude that our knowledg; in this respect, is either complete or intillible. Observations may frequently deceive us, since the

[•] It should be recollected here, that when the growth of plants is interrupted by the cold of winter, so that they no lorger get end a beneficial air to purify the atmosphere. Nature has ordered that this very cold of the winter stells contains the most effect alwirtues to stop the progress of purrelaction. We further sted, that in the most unwholesome, and particularly in marshy country, do every plants appear to be very profusely distributed, which most eminently possess the property of purifying the air. And exthe pure air, or oxygen, is of greater specific gravity than the common air of the atmosphere, it is perfectly confident with the open of nature, that the oxygen should settle towards the lower side of the leaves of plants.

human body, besides the weather, is incessantly exposed to the effects of other external agents, which may easily clude our attention. Further, the atmosphere furrounding us, besides the properties cognizable by our senses, or discoverable by the affistance of particular instruments, may also be impregnated with substances which have hitherto escaped our researches, and which nevertheless may have the power to effect important changes. Lastly, we ought not to consider the arguments deduced from analogy as strictly conclusive; we should remember, that the effects of external objects on the living animal sibre are, in many instances, totally different from those which they produce on lifeless or inanimate bodies.

Recommending these general remarks to the consideration of the reader, I proceed to consider those particular and positive effects, which the different states of the atmosphere produce on our frame, and in what manner

they influence our health.

Warm air relaxes the folid parts of the body, and occasions a stronger circulation of the fluids. Heat is chiefly oppressive to the Nerves; hence the tender and infirm suffer severely in hot weather; hence arise hysteric and hypochondriac complaints, convulsions, and diarrheas. Cold renders bodies more compact, particularly the folid parts of the animal structure, such as the muscles, nerves, bones, &c. They become more classic in winter; the appetite for food is stronger, and digestion easier and quicker. On the contrary, the resistance

of the fluid parts becomes fo great, that even the increased powers of the solids cannot overcome it, if the cold be too violent. In winter the blood is much disposed to inflammations; hence stitches in the side, inflammatory fore throats, rheumatisms, &c. In persons who take little exercise, the sluids are apt to stagnate, and the solids to chill during the winter;—upon the whole, however, the essess of cold weather may be rendered less hurtful, and even salutary to the body, if proper ex-

ercise be not neglected.

Damp or moist air fuddenly relaxes and debilitates; it occasions a slowness in the circulation of the fluids, which gives rife to obstructions, and impedes both the circulation of the blood and the fecretion of humours, by checking insensible perspiration. If the moisture of the air increases, we experience an unaccountable torpor and ennui; with the loss of energy we lofe our gaiety, and the mind is depressed with the body. Damp places and districts are always unwholesome, but more particularly fo in cold weather. Moifture, by diminishing perspiration, produces disorders of the throat, the breast, and the abdomen. But the most dangerous and fatal effects on the human body have been observed to arise from moist air accompanied with hot weather; for, when moisture has impaired our energy, heat increases the evil in a great degree, by opening the pores through which the moisture penetrates into the body, and predisposing every part of it to putrefac-tion and dissolution. This accounts for the great mortality prevalent during the hot feafon at Batavia, and fome of the West India islands.

Dry and cool air, from possessing a due degree of elasticity, promotes in an extraordinary degree the serenity and alertness of mind and body; hence it is found uncommonly salubrious to hypochondriacs. But a dry and very cold air generates inflammatory diseases; because it inspissates the blood. Dry and hot air affects us like heat, and enervates the body. But a dry air, which is not too warm, is both agreeable and healthy.

Great and fudden changes from a warm to a cold, or from a light to a heavy air, are highly injurious to valetudinarians, and even to the healthy. Soldiers in camp, and, fometimes, travellers, feel very feverely the bad effects of cold and moist night air, after long marches and journeys. Weakly and infirm persons have frequently ominous sensations, previous to any remarkable change of the air.

A moderately heavy and elastic air is the most agreeable and salutary to the human body; hence nature has not assigned us our constant residence on the summits of mountains. Yet a light and raresied air, such as is selt on the highest mountains, is not so unsit for respiration, nor does it manifest so noxious an influence on the human body, as was formerly believed. The latest travellers assure us of the contrary, and speak in decisive terms of the falutary effects of the air, during a short stay in those elevated regions.

Among the different winds--which are nothing else but strong commotions of the air—the long continued North wind is comparatively the most wholesome; it purifies the atmosphere of noxious vapours, renders the air ferene and dry, and thus imparts to the human body elasticity, vigour, activity, and a lively colour. It is, however, troublesome to persons of delicate habits, and occasions in them coughs, inflammation of the throat, pains in the side, obstructions, and febrile difeases. The South wind weakens and relaxes the body, and is very apt to produce catarrhal affections. The Morning wind is very drying; but Evening winds are cool and moist, being frequently accompanied with rain and changeable weather. All these winds differ materially in their qualities, from local circumstances, and accordingly as they blow over a Continent, over the Ocean, or over high mountains and icy regions, from which they carry along with them more or less of cold and humid particles. But upon the whole, too dry weather is always more healthy, than that which is too moift.

Of the four Seasons of the year, the Autumn is the most unhealthy; because then the particles of perspiration not only remain on the body, but are in a state inclining to putresaction. This disadvantage, however, may be easily obviated by guarding ourselves with proper dress and choosing a suitable diet. Too light a dress, and too thin stockings, are not advisable at this season. The Spring season is, in general, the most healthy. Spring,

and the beginning of Summer, are most falutary to children and young persons; while the Summer, and the beginning of Autumn, agree best with the aged. The latter end of Autumn, and the beginning of Winter, are commonly the most healthy seasons to persons of

a middle age.

It has been remarked by medical men, that certain diseases appear and disappear according to the different seasons. Thus, putrid and bilious disorders prevail in Summer; inslammatory diseases in Winter, and the catarrhal, mucous, and gastric or stomachic affections, in Spring and Autumn. It has been further observed, that in Spring the blood usually circulates more freely; hence probably arose the ancient practice of blood-letting, and taking laxatives at certain regular periods; both of which I have already pointed out, in the preceding Chapter, as dangerous in their tendency, and always hurtful to the healthy.

As the vegetable kingdom is renewed in Spring, and as vegetation, in general, is most lively in that season, there can be little doubt, that the pure vital air is then most copiously evolved, by means of the solar light and heat. Hence it follows, that the vernal air is more wholesome than that of Autumn, which is saturated with corrupted and putrifying particles. Still the cold of Autumn, and the frequent winds then prevalent, prove extremely efficacious in counteracting the baneful effects of corruption and putrefaction.

If the temperature of the air correspond with the natural constitution of the season, we may expect what is called a healthy year, and that the prevalent diseases will be of a mild nature; but if the weather does not agree with the general laws of the season; if, for instance, the Winter prove warm, or at least moderate, or the Spring cold and severe, with sudden alternations of heat, we may expect to find the year pretty generally marked with serious and obstinate diseases.

The temperature of the air depends not a little on the natural fituation of the country, whether it lie high or low; whether its mountains oppose or give a free passage to the winds; whether it contains flowing or stagnant waters or morasses, and whether it is open or covered with woods.—Country air, upon the whole, is always purer than that of towns,

narrow streets, and crowded buildings.

All strongly-scented bodies are more or less pernicious; as well those of a disagreeable smell, as the greater number of fragrant perfumes. The latter, if too strong, are more particularly dangerous, as a sense of disgust does not naturally incline us to avoid them. Among these may be comprehended all vegetable odours strongly volatile and pungent, and which thereby stimulate and stupisy the nerves. Hence people, who carry large nosegays in the hot days of summer, are apt to teel themselves variously and strongly affected, particularly with drowsiness. From this apparently innocent cause, head-achs, vertigoes, fainting-sits, and apoplexies have frequently

been produced in persons of a plethoric habit. These, as well as people of a delicate constitution, are liable to fuch affections, from the fragrance of many balfamic plants, but particularly from the strong scent of lilies, roses, pinks, the blossoms of oranges, hyacinths, and the like.—Many flowers emit a more powerful fragrance in the night than in the day-time, and the effluvia of several trees and other vegetable bodies are peculiarly dangerous, and fometimes mortal. Of this nature are the walnut and yew trees, under whose shades persons have actually died, who had fallen afleep; and likewise the deadly Upas of Surinam, and the no less poisonous Manchineel tree of the West Indies.

Aromatics of every kind taint the air in a fimilar manner, introducing into the human body particles foreign to its nature, all exciting more or lefs an inclination to fleep. Saffron and hops have fometimes proved fatal; the former in particular has often produced a fleep terminating in death, in those incautious individuals, who had lain down in the ware-houses or upon the bags, in which it was packed. Ambergris and musk are also, on account of their powerful fragrance, very hurtful to persons of an irritable and nervous temperament.

Dwellings in the vicinity of lakes, fens, and marshes, are exposed to all the noxious effects of a moist atmosphere, namely, to the various species of intermittent severs or agues;—on the other hand, it has been observed, that persons living on the banks of rivers, though at times subject to these, are not very liable to

other diseases, and that running water has a tendency to purify the air, when it is saturated

with inflammable particles.

Too fudden a transition from warm to cold air, or the reverse, is pernicious; but to exchange, however fuddenly, an unhealthy atmosphere for a healthier, is at all times safe and highly advisable. Numberless instances have proved, that fuch as were constantly indisposed in the corrupted air of a town, very quickly recovered their health, on removing to the purer atmosphere of the country. Yet the question, Which air is the most wholesome to live in? will admit only of a conditional anfwer. We must attend not only to the particular constitution of the air, but also to the nature and habits of the individual. Neither fhould we too haftily pronounce every air unwholesome, that does not appear to agree with us. The air of every climate, whether hot, cold, or temperate, may be called healthy, provided it be pure and clear, and occasionally agitated by wind: but a gross atmosphere, and one loaded with animal or vegetable exhalations, is certainly deleterious. After all, perhaps the longevity of the inhabitants may be considered as the best evidence of a healthy district. Thus we find uncommonly longlived persons in high countries, or such as are visited by frequent winds, and also in small fea-port towns. In villages and places thinly inhabited, the proportion of aged people is confiderably greater than in cities or populous towns. This may be afcribed partly to a lefs degree of corruption in the air, and partly to

a more simple mode of life prevailing in such places: for wealth and riches, the concomitant effects of which are greater luxury and extravagance in living, usually keep pace with the increase of population; and if the numerous chimney-sires of our populous cities did not serve as so many well-contrived machines for rarefying the atmosphere, incalculable mischiefs must inevitably ensue.

Of the Improvement of Air in Dwelling-Houses.

A House built on a rising ground, on a healthy foil, in an open, dry country, and neither exposed to the greatest degree of cold in winter, nor to the highest point of heat in fummer, may be faid to stand in a healthy situation. Hence those apartments are the most healthful as well as comfortable to the individual, which enjoy a pure and free circulation of air in fummer, and the cheering rays of the fun in winter: the heat of summer bcing confiderably tempered by the former, and the feverity of winter much abated by the latter. Farther, a proper fize and height are requisite to constitute a healthful apartment; for low rooms are detrimental to health, particularly when inhabited by large families, and feldoin aired, or rather, which is frequently the cafe, when all air is carefully excluded by close doors, shutters, curtains, &c. The most proper place of residence in winter is one with a fouthern aspect, not only as being more dry, but also more cheerful, and therefore attended with a favourable influence on the spirits. In summer, the situation of a room may be chosen either to the North or to the East, the latter of which is preserable, because it admits the first enlivening rays of the Sun.

Although it is not in every person's power to choose his habitation agreeably to the laws of health; yet this choice of a pure and healthy air is not sufficiently attended to, and it certainly deserves as much consideration in purchasing an estate or country-house as the quality of the soil or other lucrative advantages.

The local conftitution of the air depends not merely on the exhalations of the foil itself, but likewise on the different vapours, conducted to and blended with it by the winds, from adjoining places. Thus in a dry and sandy country, considered of itself as healthy, the air may be rendered extremely unwholestome from the vicinity of marshes or other stagnant waters.

The better to judge of the falubrity of the air in any district, we should examine the properties of the wells and springs; for both air and water absorb the saline and mineral particles of the soil. We may pretty certainly conclude, that a country producing good water, enjoys likewise a salubrious air; and as the best water is tasteless, so the purest air is free from any smell whatever.

The most certain marks, by which to distinguish whether the air in rooms be damp or not, are the following: the walls or tapestry change their colour; bread in closets acquires a mouldy surface; spunges in the rooms retain their moisture; loaf-sugar turns soft; iron rusts; brass and copper acquire a green colour, or verdigris; and wooden furniture moulders and crumbles to pieces.

The fitting-room ought, if possible, to be above the ground floor, or in the second story; it should be so constructed as to admit a free current of air; but if this cannot be done, it should be frequently aired by opening the windows in dry weather, or by sumigating the room, either with vinegar dropped-upon warm stones, or evaporated in a bason over a lamp, or with sugar, juniper-berries, and the like.

Every room is filled with three different strata of air: 1. The lower part of the room contains the heaviest species of air, namely, sixed or carbonic acid gas, particularly in apartments situated on the ground-sloor, or even under ground; 2. The middle part of the room is silled with the lighter atmospheric air; and 3. The uppermost stratum contains the lightest or inslammable air, the most corrupted of the three, in consequence of the processes it has undergone by respiration and combustion. In losty apartments this contaminated species of air is not inspired by the lungs; because the middle stratum, or the most wholesome of the three, extends to a height above that of a man.

A continual change of the air, by opening the doors and occasionally the windows, however advisable, is yet not sufficient to preserve a healthy atmosphere in an apartment. For this important purpose the following improve-ments may be suggested as useful: 1st, Small apertures in the ceiling of the room, or through the walls close to the ceiling, in an oblique direction, fo that the rain and fnow cannot penetrate into it; 2d, Ventilators, that is, finall moveable wheels made of brass or sheet-iron, which are applied to some part of the window-panes, and fet in motion by the pressure of the external air. This is an excellent contrivance to introduce fresh atmospheric air into a room, by occasionally opening and shutting the door. The most proper height for placing these ventilators is about seven feet from the sloor; 3d, Air-tubes running in a straight direction from the door to the fire-place, or rather to the wall of the chimney, and concealed under the floor of the room. As fuch tubes, however, are very expensive, and appear better calculated to convey the fmoke up the chimney, after all means have been tried in vain, than to conduct the corrupted air from the upper part of a room, I shall mention a better and much easier method of effecting this purpofe. It is a late discovery of a physician in France, who contrived it with a view to fave the great expense of ventilating or airing large wards in hospitals, filled with patients who laboured under putrid distempers, particularly in the heat of summer. He caused a number of small holes to be made in the uppermost part of the window-frames; into these holes he placed from without an equal number of funnels, presenting an aperture of nine or twelve inches diameter, and terminating in the infide almost in a point, or at least in an opening not exceeding the fize of a small quill. By means of these simple machines, the air in the sick rooms was so effectually renewed, by the great and constant pressure of atmospheric air from without, that any other artificial process for correcting the putrid air in a large hospital

was judged to be unnecessary.

Above all things, the windows and doors of fitting and bed-rooms, when it can be done conveniently, ought to be left open for a certain space of time, every day. This, however, requires to be done at the proper time, neither too early in the morning, nor when it grows dark in the evening, during the vernal and autumnal months; nor at the time when the horizon is overspread with a thick fog. The windows should be opened, when the air is pure and ferene; or, in general, when there is less danger to be apprehended from the external air than from that within. Sometimes it may be proper to make use of what is called pumping the room, or moving the door backward and forward for some minutes together; but in spring and autumn, our fitting-rooms, and even in winter, bedrooms, ought to be perflated every clear day, by currents of fresh air, for a considerable time.

In the hot days of fummer, the windows may be opened early in the morning and in the evening, in order to cool and refresh the heated air of the room by that from without.

It is however not fafe (and has fometimes proved fatal) to leave the windows of a bedroom open at night during the fummermonths, as there is no finall hazard of checking perspiration by the cool night-air; the susceptibility of the pores being then very much increased by the heat of the day, and the warmth of the bed. Rooms which we inhabit in the day-time may be safely left open during the night. In summer-houses, or such as are surrounded with plants and trees, it will be proper not to open the windows of bed or other rooms, till some time after sun-rise, and to shut them at sun-set: they require also to be opened and shut sooner in hazy than in screne weather.

The airing of apartments should not be neglected even in winter, as coal-sires alone are not sufficient to carry off the corrupted particles of air, unless they be assisted by ventilators.—Here I must oppose and contradict a prevailing, yet mistaken notion, that fire in a room where the windows are open, introduces moist air. On the contrary, the most proper time for opening the windows is after lighting up a brisk fire; as the warmer air of the room will then be powerfully attracted by the colder atmospheric air, and the corrupt particles of the air within most speedily dissipated.

In moift and cold air, the dress should be somewhat warmer than usual: Flannel may then be worn with double advantage next the skin, and the rooms we inhabit should be warmed, or at least sumigated, with the ber-

ries of Juniper or similar shrubs. Fumigation is likewise attended with this advantage, that it contributes to dry and in some degree to warm the air.

In moist and warm air the explosion of a little gunpowder will be of use, or vinegar may be evaporated with greater safety, and the stoor and walls sprinkled over with this ex-

cellent antiseptic.

Hot and dry air may be tempered by placing vessels silled with cold water in different parts of a room; or, as is often practised in hot climates, by sprinkling water over the sloor. The greater or less degree of corruption of the air, in an apartment, depends very much on the kind of labour or exercise performed in it: Six watchmakers will not corrupt the air nearly so much as two carpenters would do in the same space and time; hence appears the necessity of appropriating losty rooms instead of low garrets, for the workshops of mechanics.

Green plants and flowers placed before the windows are both an agreeable and useful ornament, if not of too strong a fragrance. In serene weather, it may be expedient to strew fresh plants (not flowers) in a dwelling-room, exposed to the rays of the sun, taking care, however, to remove them as soon as the sun withdraws. This method of exposing plants, or even the branches of trees with green leaves, in apartments, may have a beneficial influence on valetudinarians, and particularly on asthmatic persons, as vital air, or oxygen is

thereby generated, and introduced very grad-

ually into the lungs.

Large trees with thick foliage should not be placed very near the windows of a house; for, besides that they obstruct the access of day-light and fresh air, and have thus a tendency to make the rooms damp, their exhalations in the evening, and during the night, are by no means wholesome. Trees planted at the distance of eight or ten yards from the house, do not prevent the free access of air; they present an agreeable object to the eye, and cannot be too much recommended, both on account of their cooling shade in summer, and the salutary exhalations they emit during the day.

It has been already mentioned, that the burning of candles corrupts the air; for which reason the custom of illuminating assembly or other large rooms, with a *superfluous* number of candles, must be very detrimental. This extravagance becomes still more dangerous in places where, beside the crowd of people, great quantities of provisions, dressed with the richest spices of the East and West, contribute to saturate the air with the most heterogeneous particles. And as persons of tender lungs must suffer extremely in such an atmosphere, it would be proper to provide all public rooms with a competent number of conic ventilators, of the description before mentioned.

Strictly speaking, we ought not to sit in the room where we dine, or take victuals, until it be aired again: those who can afford this luxury, should be careful not to stay for hours.

together over their bottle in the dining-room; the bad effects of such contaminated air are not perceived by the persons continuing their libations after dinner, but are very sensibly felt by any one coming in from the fresh air.

It is no less unhealthy to sleep in a room where a quantity of green fruit is kept, a circumstance not attended to in country places, particularly by those who deal in fruits. From its fragrance a portion of inslammable matter exhales, which soon impregnates the air. Hence females of delicate habits have been known to faint, in approaching places where a few quinces were kept. For the same reason, store-rooms and pantries are extremely unwholesome, if provisions of all kinds, animal as well as vegetable, be kept in them; especially oil, candles, fat, sless meat, whether raw, boiled, or roasted, pastry, and the like. As foul linen readily imbibes the perspira-

As foul linen readily imbibes the perspirable matter of the skin, it should never be suffered to remain any time in a bed-room, or

fitting-room.

If possible, we should not sit through the day in a room in which we have slept; as the bed-clothes, and particularly feather beds, very slowly part with the exhalations they have imbibed during the night, neither is it sufficient for purifying the air of the room, that it has been ever so well aired in the morning.

The vapour of charecal produces, particularly in close apartments, dangerous and frequently fatal effects. It fills the atmosphere with sulphuric particles which may be inspired, but cannot be expired:—they retard the

motion of the blood-vessels, stagnate the blood itself, penetrate into the head, and produce an acute pain, vertigo, and torpor. Hence the greatest precaution is necessary, where charcoal is used, as innumerable statal accidents have happened from this source. Dyers, who employ it for drying their cloth upon frames, seldom sail to experience great injury to their health.

All employments, in which perfons work among impure wool, oil, colours, and the like, are to a certain degree detrimental to health. Washing, ironing, dressing the hair with greafy curling-irons, burning lamp oil, frequent painting of the walls, all faturate the air of a room with pernicious damp and sulphuric vapours. From the change, which oil and candles in a state of combustion produce in the colour of a white wall and white curtains, we may infer, that this fetid steam must also penetrate into the human body, and if so, must materially affect it.

It farther deserves to be remarked, that all damp vapours are prejudicial, although they should not in themselves have a tendency to corrupt the air. Hence the keeping of wet linen, or even wet clothes, umbrellas, and the like, in dwelling-rooms, should by all means be avoided. Mechanics and others, who are obliged to dry wet things in their strongly heated apartments—joiners, turners, potters, bookbinders, &c. are particularly liable to swellings, and other disagreeable affections in

the relaxed veffels of absorption.

Of Heat and Cold ..

As observation and experience inform us, that immoderate heat relaxes the body, overheats the blood, and exficcates or confumes the other fluids; and that the people who live in temperate regions are more hardy and. vigorous, and attain to a greater age, than the inhabitants of warmer climates; it follows from these premises, that we ought not to enervate the human body by keeping it immoderately warm, by dreffing it with a fuperfluity of clothes, by plunging it unneceffarily into hot baths, by using too strong fires in temperate weather, or least of all, by sleeping in warm rooms, and perhaps on the most; heating of all fubstances, feather beds. The temperature of a fitting-room should not excced 60° of Fahrenheit's thermometer; that of a bed-room may be about 50°, as the medium temperature of, our climate, is between: 50 and 55°:

Although man is, no doubt, capable of inuring himfelf to a very great degree of heat as well as of cold, yet fudden changes can be fupported only by the few who posses very hardened constitutions. The gradual changes of the feasons prepare us in the safest manner to sustain all the alternations of cold and hot weather. It is therefore an error, and of no small consequence, in the modern system of education, that we generally endeavour to habituate our children to the support of cold weather only. Persons who cannot bear the heat of the sun, or strongly heated rooms, are, from their excessive delicacy, frequently exposed to the most violent, nay to mortal accidents. Hence children ought to be slowly and gradually accustomed to these inconveniencies, which indeed occur frequently, and are more dangerous than those arising from sudden transitions to a colder temperature: for the effects of the latter may, in a great measure, be obviated by exercise and muscular action.

In the fultry days of fummer, we should be particularly on our guard against violently overheating the body; -in autumn, we should not dress too lightly, and in the mornings and evenings always fomewhat warmer; -in fhort, we ought to avoid every thing that appears likely to check and repel perspiration. The baneful custom of accommodating our dress to the almanack and the fashion, rather than to the viciffitudes of the weather, in this inconstant climate, must necessarily be productive of many disagreeable consequences. Above all things, we ought to change our fummer-dress pretty early in autumn, and to clothe ourselves gradually warmer, according to the variations of the weather. Yet after all, perhaps it would be most advisable to accustom ourselves to one kind of dress only for all feafons. The propriety of this custom I shall more particularly consider in the fourth Chapter.

With respect to the proper time for heating rooms in autumn, it has been supposed, that early fires are unwholesome and productive of frequent catarrhs. This affertion is

certainly ill founded; for in warming a room, as well as in clothing the body, we should not so much be regulated by the particular time of the year, as the state of the weather, and the degrees of actual heat and cold: in attending to this circumstance, we cannot easily mistake. If, in the temperate days of autumn, the room should feel colder than the external air, it is time to make a moderate fire: in damp and cold weather this is an ufeful precaution, even in fummer. Those who from caprice, parfimony, or prejudice, would rather shiver on some weeks longer, than consult . their fensations, often feel the consequence of a violent cold. The Dutch and German floves certainly afford more uniform heat in a room, though they might not be confidered cheerful enough for an English company.

As we can neither breathe nor live without fresh air, we ought not to withdraw our bodies too much from the bracing effects of cold. In this respect, we should act conformably to nature, that is, in the fame degree as the warmer weather changes to a colder flate, we should gradually expose ourselves to the various changes of temperature. The cold will then neither feel unpleasant, nor impede the necessary perspiration; especially if we oppose it with vigour and bodily exercise. We ought also to take more folid sustenance in winter than in fummer; because, by the longer continued motion or digestive process of the stomach, the circulation of the blood is accelerated, from which the natural heat of the body is produced. Nature herself dictates

a compliance with this precept, as she has provided us with more substantial articles of food during the former season than the latter.

Laftly, as every fudden change of the weather from heat to cold, and the reverse, is prejudicial to the body, we ought to guard against every circumstance by which perspiration may be fuddenly checked. Hence we never should remove from a strongly heated apartment into a fresh and cold air, unless we are provided with a warmer drefs; -in hot days, or after violent exercise, we should not frequent vaults, cellars, or ice-houses, undress immediately after overheating the body, nor take rest upon a damp foil or upon stones, nor bathe in cold water. Such transgressions have often been punished with instant death, or, what is still worse, have brought on a painful and lingering species of consumption, which has hitherto baffled the united efforts of the Faculty, and which annually makes dreadful havoc among people of a middle age.* It is devoutly to be wished, that the experiments, now

^{*} According to the statement given by the Bills of Mortality, the total number of deaths in London, during the three spring months of 1799, amounted to 5271. Among these, no less than 1353, or spreards of one fourth, were carried off by confumption !- Although confumption and decline are terms often used to express many other chronic difeases, as well as pulmonary consumption, so that the above Rated number probably includes various species of decline, yet, even with these allowances, the number of victims to general consumption is truly terrific. Let the reader reflect, for a moment, on the following melancholy inference: - If the population of the country confist of between nine and ten millions, of whom the 30th or the 33d part, that is, about 300,000, die annually, it follows that this merciless disease, Consumption, cuts off about 80,000 persons every year, in Great Britain alone, and thefe generally in the prime of life, when Society ought to be benefited by their mental and bodily exertions!!

purfued with factitious airs or gases, and with the fox-glove, may afford some remedy against this formidable destroyer of the human species, which cuts off incredible numbers in the bloom of life, and spares neither age, rank, nor sex. And, as there is so much reason to believe, that a great proportion of consumptive cases originate from the sudden transitions above mentioned, no language can be strong enough to deprecate practices, as injudicious as they are destructive.

CHAP. III.

Of Cleanliness, and its various modifications, so far as it is immediately connected with Health; —the management of the Teeth;—the use of Baths, &c.

Of Clearliness in general.

HIS domestic virtue ought to extend its influence to every object connected with the human frame; to the preparation and confumption of food and drink; to dress, habitation, household furniture, and all our physical wants; in a word, cleanliness should not be confined merely to the interior domestic economy; it claims our attention in every place which we occupy, and wherein we breathe.

Let our clothes, linen, beds, covers, blankets and fheets, be clean and dry; as all these fubstances absorb perspirable matter, and check the process of perspiration. Articles of dress which are soiled, and come into contact with the skin, being placed immediately over the pores, reimbibe the humours already perspired, and return them to the body by the absorbents. Dirty linen will never attract the uscless or noxious matter, which is secreted from the blood, and ejected from the body; it remains on the pores of the skin, and is either again absorbed by the vessels, or clogs those emunctories which require always to be kept open. For a similar reason, it is highly

improper and dangerous to wear the clothes of fick perfons, especially in contagious dif-

tempers.

Let the body, and particularly the joints, be frequently washed with pure water, especially in summer, when the perspirable matter, being of an unctuous, claminy nature, obstructs the excretion by the pores. The face, neck and hands, being most exposed to the air, dust, and the like, ought to be daily washed, both morning and evening. Attention should also be paid to the ears, by cleaning them occasionally; so that the sense of hearing may not be impaired by an accumulation of wax, which from its acrid nature may prove unpleafant as well as injurious. The whole head ought to be frequently washed and cleaned, even though no hair-powder be used; as it perspires very much, and is be-sides exposed to dust and other particles in the atmosphere. Washing opens the pores, while the comb, by its close application to the skin, dissolves the viscid humours, and renders them fluid.

The mouth should be rinsed every morning, after dinner, and at night, with cold water; but in winter the chill should be taken off. The frequent washing of the mouth is otherwise necessary, because the viscid slime, and small particles of food which settle about the interstices of the teeth, are very apt to putrify, and, if not removed, will infect the breath, and gradually injure the teeth themselves. Besides, this slime settles on the tongue,

covers the papillæ by which food is tasted, and

renders the palate less sensible.

It is fcarcely necessary to observe, that the nose also should not be overlooked, as by neglecting to remove the secreted moisture in due time, the effects may become troublesome and detrimental to the organs of smell. In children, the nose ought to be occasionally washed; it having been found that the unpleasant smell, peculiar to some infants, is owing to the habitual neglect of cleaning that organ.

The tongue should be cleaned every morning, either with a small piece of whalebone, or with a fage leaf. This leaf is likewise useful for polishing the teeth. To clean the throat, we should gargle it with fresh water, and swallow a mouthful of water every morning—the latter, however, must not be attempted too hastily; but, when we once accustom ourselves to the practice, we shall find

it attended with advantage.

It is necessary, particularly in hot weather, to wash the feet frequently; as they perspire much, and are more exposed to dust than any other part of the body. The water should be warm, but not too much so, because hot water thus used relaxes the sibres, drives the blood upwards, and occasions head-achs. The proper degree of heat for young persons to wash in, is between 96 and 98° of Fahrenheit, and for the aged between 98 and 100°, or somewhat more than milk-warm.

The removing of the beard and nails is no infignificant matter in the care of health. By shaving, we promote perspiration. Long

nails, especially as they were in fashion some years ago, dissigure the hands, and prevent the feet from expanding properly: but the nails ought not to be cut too close, otherwise the toes will be obstructed in their pressure on the ground, and the singers in feeling. They may also be easily wounded; and wounds under the nails are generally attended with disagreeable consequences, on account of the many nerves running in that direction. Too long nails on the toes are apt to grow into the sless, to become an obstacle in walking, and sometimes to occasion considerable pain.

In the veffels used for preparing food and drink, we ought likewise to pay proper attention to cleanlines. Every particle of filth introduced into the stomach may prove hurtful to it, to the tender intestines, to the blood, and consequently to the whole body. For the same reason, it is not only indelicate, but also unwholesome, to dine or take any food in places where an offensive smell prevails.

On the management of the Teeth.

THE principal requisite for the preservation of the teeth is, never to retire to rest without having cleaned them: for this prevents the viscous matter of food, collected during the day, from corrupting them in the night. The tooth-ach, now so common, is frequently owing to a hollow state of the teeth, but still more frequently originates in a want of clean-

linefs. The cleaning of the teeth, however, requires precaution. What is called the Tartar of the Teeth, is of a corrofive nature, and should be removed with the greatest care. The manner in which most Dentists treat the teeth, as well as their powders, tinctures, and other dentifrices, although highly puffed off and ftrongly recommended, are obviously pernicious. They deprive the teeth of their enamel, make them loofe, and spoil the gums. The various dentifrices, whether Royal or Imperial, advertised in the public papers, are at least of doubtful, if not injurious effect. It is an aftonishing instance of credulity and infatuation, that people will take external and internal medicines upon trust, when they would hesitate to take any food, with which they are unacquainted.

If there be too much tartar, fo that it adheres like a cement between two teeth, its being incautiously removed will deprive the teeth of the tartarous cohesion, and consequently of their support; thus, from the constant contact of the tongue, lips and food, they will be shaken and loosened. The same will happen, should the tartar be allowed to eat away the gum from the root of the tooth. If in this case the foundation of the tooth be injured, it will necessarily be rendered loose, the gums being no longer able to retain a tooth, which is deprived of its intermedi-

ate cement.

The tartar therefore must not be broken, all at once, with iron or glass instruments; but may be gradually scraped away with

blunt or broad cut quill, or some similar substance, from which the enamel of the teeth can fuffer no injury. Most kinds of dissolvent drops, especially those fold as specifics for whitening the teeth, are made up of vitriolic acid, diluted with fome distilled waters-They are of no service, but, on the contrary, remove the enamel with the tartar, and thus spoil the teeth for ever. The common tooth-brushes

are liable to the same objection.

To prevent the tartar from fettling on the teeth, they ought to be kept clean, by washing them every morning and evening. Certain articles of food and drink should likewise be mentioned, as having a tendency to produce and accumulate the tartar-fuch are all viscous and saline substances, as salted and smoked meat, cheese, roasted eggs, the flesh of tame and wild animals kept too long for the fake of making it more tender and palatable, truffles, and all species of mushrooms; beans, peas, chefnuts, vinegar, tart wines, and all kinds of acid fruits.

An expedient equally fafe and effectual, for removing the tartar, is, to cover the teeth with a fine powder of Gum Tragacanth, or with foft wax, and by that means to extract the tartar at once, together with this adhe-

five covering.

Although it does not enter into the plan of these Lectures to treat of the various diseases to which the teeth are subject, or to describe the different methods purfued in curing them, yet I judge it necessary to point out some of the most simple and approved remedies in that

very painful affection, the tooth-ach. If the complaint proceed from a hollow and carious tooth, fome foft extract of the Peruvian Bark may be placed in the cavity of the tooth; if this should not remove the pain, a few drops of Cajeput vil upon cotton may be applied to the hollow tooth, or rubbed externally upon the painful side of the cheek. Thunberg, the Swedish Traveller, introduced the use of Cajeput oil into Europe, having often witnessed its powerful and almost instantaneous effects in the East Indies, where it is the last and only comfort of gouty and rheumatic sufferers.

Dr. Richter, an eminent Physician of Göttingen, informs us that he has frequently relieved the most violent tooth-ach, by applying externally the effence of pimpinella, or Burnetfaxifrage, with an equal quantity of laudanum, adding to it a drop or two of the essential oil of cloves. Though external remedies are not likely to effect a radical cure of this. malady, yet in urgent cases they may be safely reforted to, especially if applied so as not to injure the skin of the face; for they will often produce a temporary relief. If, however, the tooth-ach proceed from no local cause; if, for instance, it be owing to a corrupted stomach, to catarrhal, rheumatic, hysteric, venereal, or other affections; all the specifics ever discovered cannot remove the pain, until the cause also be, wholly or in part, removed. In my own practice, I have found the oil of Savin, or Juniper oil, preferable to laudanum, in its effects on a hollow tooth; the latter is at best an uncertain remedy.

In scorbutic affections of the teeth and gums, a vegetable diet, confifting chiefly of ripe fruit, and mucilaginous vegetables, will be found the best corrective. Beside these, a fine powder, made of three parts of doublerefined fugar, and one part of burnt alum. may be employed with advantage for the purpose of rubbing them. Sugar is an excellent antifeptic; and IMBERT DE LONNES, a French Phyfician, reports, that a whole ship's company was once cured of an alarming scurvy, by living for some time, from necessity, upon fugar alone. We should also consider the connexion subfifting between the teeth and the stomach; if the former be unequal to the purposes of mastication, the digestive powers. will be gradually impaired, and the foundest stomach corrupted. To neglect the teeth, therefore, is to neglect the stomach; and if the stomach be weakened, the whole mass of the fluids, and particularly the blood, will ultimately be tainted with crude, unaffimilated, and acrimonious humours.

To diffolve and wash away the superfluous, slimy, and unctuous matters which produce the tartar, fresh water is sufficient; or it may be rendered a little more acrid by the admixture of a small quantity of common salt. Acids and alkalies, so frequently employed as dentifrices, are of too corrosive a nature; and alkalies in particular injure the gums, perhaps the teeth themselves, while acids deprive them of their enamel, and thus occasion a speedy external corruption and inevitable gangrenc within.

The most simple dentifrice is a crust of bread hard toasted, and reduced to a sine powder. This is fully calculated to absorb the viscid, oleaginous particles, and to remove the stony or tartarous matter. The bread, however, should not be toasted too black, as in that case it would evolve an acrid alkaline salt, which might prove hurtful. A still better dentifrice is a moderately sine powder of the Peruvian Bark, particularly of the genuine red species, which strengthens the gums, without instaming them.

In cleaning the teeth we ought not to make use of brushes or sponges, but of the singer, which being provided with the sinest papillary vessels, is a much better and more proper instrument, and precludes the necessity of resorting to artificial means. Besides, the singer has the advantage of being soft and pliable, and of feeling any immoderate pressure too sensibly, to permit us to do injury to the teeth or gums:—hence, it is an ill-judged delicacy alone which can prevent us from making use of it, preserably to even the best tooth-brushes.

For cleaning the interftices between the teeth, we fliould not employ pins or needles, whether made of gold, filver, or fteel; for all metallic fubftances are apt to canker the teeth. If toothpicks be at all advifable, they should be made of foft wood, or quills cut in a blunt point. In my own opinion, none should be used; for, of whatever materials they are made, they open, loosen, and injure the teeth, by making room for the tartar and

other matters, to prey upon the teeth and gums. To answer every purpose of toothpicks, a thick and soft cotton cloth should be used, to rub the teeth over gently after every meal: but if people have once accustomed themselves to regularly picking their teeth, then indeed the cotton frictions may perhaps be too late.

Lastly, the cleaning and brushing of the teeth, however useful and necessary, is insufficient to prevent the settling of the tartar, and the consequent injury to the teeth; for the source of both evils does not exist in the mouth, but really proceeds from the stomach, and a corrupted state of the sluids. For this reason, the medical treatment of the teeth requires a particular regimen and diet, according to the individual case of every patient.

Of the Use of Baths.

THIS important branch of dietetic regimen is of excellent use and efficacy, both in the cure and prevention of diseases. Though the ancients could less dispense with the use of the bath, on account of the frequency of their athletic exercises, as well as from the want of linen, which was then much less in use than at present, yet in our times it would be of great service, if the use of baths were more general and frequent, and this beneficial practice not confined to particular places or leasons, as a mere matter of fashion. Con-

fidered as a species of universal domestic remedy, as one which forms the basis of cleanlines, bathing, in its different forms, may be pronounced one of the most extensive and beneficial restorers of health and vigour. I am not so sanguine, however, in my expectations, as to think that the cure of all maladies and diseases may be effected by the bath, as was lately promised by a noted empiric in this country, who most sagaciously impregnated his vapour baths with the collective produce of the vegetable kingdom. Such a general remedy is just as chimerical as the most famous panaceas, the tincture of gold

not excepted.

Bathing, whether in warm or cold water, produces the most falutary effect on the abforbent vessels; which would otherwise reconduct the impurities of the skin through the pores, to the no small injury of health. To those in a perfect state of vigour, the frequent use of the bath is less necessary than to the infirm; as the healthy possess a greater power to relift impurities, by means of their unimpaired perspiration, the elasticity of their minute vessels, and the due consistence of their circulating fluids. The case is very different with the infirm, the delicate, and the aged. In these, the slowness of circulation, the viscidity or clamminess of the fluids, the constant efforts of nature to propel the impurities towards the skin, combine to render the frequent washing of their bodies an essential requisite to their physical existence.

Baths, considered as the means of curing diseases and restoring health, if judiciously applied, are likewise of peculiar advantage; and though, in this respect, they do not properly make part of a regular system of dietetics, yet I shall request the indulgence of the reader, while I make a few necessary remarks relative to the proper application of the bath, it being so frequently used as a mere dietetic remedy. Much depends on a clear and accurate knowledge of the properties and essential strength of the different baths. I shall therefore divide them into two principal classes, the warm and the cold bath.

The warm, that is, the tepid or lukewarm bath, being about the temperature of the blood, between 96 and 98° of Fahrenheit, has usually been considered as apt to weaken and relax the body; but this is certainly an ill-founded notion. It is only when its heat exceeds that of the human body (as in the Hot Bath and King's Bath at BATH, both of which are from 18 to 20 degrees higher than blood-heat) that the warm bath can produce a debilitating effect. Indeed, baths of the above immoderate heat ought not to be used in their natural state, that is, without reducing their temperature by cold water, except in particular cases, and under the immediate advice of a physician. On the contrary, the lukewarm or tepid bath, from 96 downwards to 85, is always fafe; and is so far from relaxing the tone of the folids, that it may justly be considered as one of the most powerful and universal restoratives with which we are

acquainted. Instead of heating the body, it has a cooling effect; it diminishes the quickness of the pulse, and reduces it in a greater proportion, according as the pulse has been more quick and unnatural, and according to the length of time the bath is continued. Hence tepid baths are of eminent fervice, where the body has been over-heated, from whatever cause, whether after fatigue from travelling, or fevere bodily exercile, or after violent exertion and perturbation of mind; as they allay the tempestuous and irregular movements of the body, and confequently, in the strictest sense, invigorate the system. By their foftening, moistening, and tumifying power, they greatly contribute to the formation and growth of the body of young persons, and are of singular benefit to those, in whom we perceive a tendency to arrive too early at the confishence of a settled age; fo that the warm bath is particularly adapted to prolong the state of youth, and retard for fome time the approach of full manhood. This effect the tepid baths produce in a manner exactly alike, in the coldest as well as in the hottest climates.

From what has been advanced, it will not be difficult to discover, in what particular disorders the tepid bath may be of the greatest service, and the reason why they prove so eminently useful (particularly in a parched and rough state of the skin) in paralytic, spasmodic, bilious, consumptive, hypochondriac, hysteric, and insane cases, as well as in an actimonious and corrupted state of the sluids,

fuch as scorbutic and leprous eruptions, lues, &c. One obvious effect of the habitual use of the bath, particularly the tepid, is, that it foftens and renews the external integuments of the body. It considerably increases the pressure on the body from without; hence breathing, particularly on entering the bath, is frequently fomewhat difficult, until the muscles have by practice become inured to a greater degree of relistance. Yet this effect, which in most instances is of small importance, requires the greatest precaution in some particular cases, so far as to prevent the use of the bath altogether; for instance, in persons of a full habit, who are in danger of breaking some of the internal blood-veilels, by the precipitate use of the bath, whether warm or cold.

These few hints will be sufficient to determine the cases, in which the lukewarm bath may be resorted to with safety and advantage, as a dietetical remedy. Its application in the treatment of diseases is foreign to the object of this Chapter, and demands the most minute inquiry into the nature of the cases which indicate the use of it, as it is of itself a potent remedy, which, if improperly used,

may produce a contrary effect.

Bathing in rivers, as well as in the fea, is effectual for every purpose of cleaning the body; it washes away impurities from the surface, opens the cutaneous vessels for a due perspiration, and increases the activity of the circulation of the blood. For these reasons, it cannot be too much recommended, not only to the infirm and debilitated, under cer-

tain restrictions, but likewise to the healthy. The apprehension of bad consequences from the coldness of the water, is in reality ill-founded; for, besides that it produces a strengthening esset, by its astringent property, the cold sensation is not of itself hurtful.

The fame precaution, however, is requifite in the use of the cold as that of the tepid bath; for after having overheated the body, especially in the hot days of summer, it may prove instantly fatal, by inducing a state of apoplexy. Hence the plethoric, the afthmatic, and all those who perceive a great determination of the blood to the head, should be very circumspect in its use. For although the confequence may not prove immediately fatal, yet the too great strain and pressure may easily burst some of the smaller blood-vessels in the head or breast, and thereby lay the foundation of an incurable diforder. To fuch as are of a found and robust constitution, bathing may be rendered an agreeable exercise, by swimming against the stream; for, the sibres and veffels being obliged to refift the power of the undulating waves, the nerves are thereby excited into action.

Before I proceed to lay down dietetical rules for the use of the bath, I shall premise a brief historical narrative of this excellent practice, and generally explain its sensible effects.

Among the Greeks, and particularly the Spartans, bathing was not intrusted to the caprice of individuals, but considered as a public institution, being governed and arranged agreeably to the express laws of the State. We

learn also from Sacred History, that among the Jews, at a much earlier period, persons under certain circumstances were pronounced unclean, and confequently unfit to hold any intercourse or communion with others, until they had performed the appointed ablutions. The Greeks, according to their own historians, learnt this practice from the Egyptians, and the Romans from the Greeks. those celebrated nations, public and private baths formed an important branch of useful and ornamental architecture. Many opulent individuals courted the favour of the people by lavishing their treasures in the establishment and decoration of public baths; and to this day we frequently discover the valuable remains of these national edifices. Among the Romans, the baths were in time converted into regular and luxurious dwelling-places; in which the fons of the patricians and of the wealthy were educated; a circumstance sufficiently afcertained in the history of CHARLES the Great.

The changes which the contact of cold water produces on the body, naturally lead us to inquire into the physical nature and properties of the cold bath. The lightest water is at least 800 times heavier than air; from which it has been concluded, that the former presses upon the human body with a force proportionally great. If, therefore, the column of air, which presses upon our body with a force equal to 39,900 lb. could be converted into water, the whole weight of that pressure would amount to 31,920,000 lb. Yet, as our health-

is affected by a difference in the pressure of the air, occasionally varying from 3 to 4000lb. we may easily understand, that the human body is not calculated to sustain, for any length of time, the great pressure of water. From this cause, the most experienced negro divers dare not venture beyond a certain depth of the sea; well knowing it would be impossible to rise up against the additional weight of wa-

ter incumbent upon their bodies.

The fenfible properties of the Cold Bath, in general, confift in its power of contracting the folid parts, and of inspissating the fluids. Any part of the body, which is exposed to the fudden contact of cold water, experiences at the fame instant a degree of tension and contraction, and becomes narrow and fmaller. Not only the blood-veffels, but likewife the fmall capillary tubes, are liable to this contraction and subsequent relaxation. What is vulgarly called goofe-skin is an effort of the cutaneous fibres, a contraction of the orifices of the absorbent and exhalant vessels, occasioned by mental perturbation, spasms, or the effect of cold.—Hence it happens, that by the cold bath all the blood-veffels of the skin, and of the muscles in immediate contact with it, are so constricted and diminished, that at the time of this violent exertion they are unable to receive the usual quantity of blood. The smaller vessels of the skin are likewise closed, and press upon the humours contained in them, so as to prevent all perspiration during this pressure. Thus all the fibres of the skin and muscles are brought into close contact; and if the humours contained in these tubes had no other outlets, by which to discharge themselves, they would become thick or inspissated, and lose their natural warmth. Were this infpillation of the fluids really to take place, it would be attended with dangerous stagnations and obstructions. That it does not, however, produce these fatal effects, may be afcribed to the following cause. As soon as the pressure is made against the external vessels, the blood retreats from them, in search of places where it may find less resistance. All the great veffels within the body afford receptacles, into which it now flows, till the principal arteries, and the veins of the inteftines, being filled, extended, and enlarged, it rifes to the heart. Although the effect confequent on the cold bath may be confidered as altogether mechanical, yet this fimple operation is frequently productive of the most important and beneficial effects.

All other strengthening remedies, operating, in general, only on the sluid parts of the body, require to be previously disloved by the sluids, blended with the mass of blood, and thereby conducted to the folid parts. The cold bath, on the contrary, acts almost instancausly on the folid parts themselves, and produces its bracing essect, before a single drop of blood has been commuted. From which remedy, therefore, is it most likely we should derive the desired essect; that which immediately answers the purpose, or that which must pass through so many canals, and undergo so many changes, before it arrives at the

S 2

place where it is to exert its efficacy? The fudden changes arifing from the application of the cold bath contribute in various ways to brace the human body. The relaxed fibres of the skin and the muscles acquire more solidity and compactness from contraction. Their elasticity is increased, and thus a considerable defect removed: the nerves are stimulated and incited to those powerful exertions, on which the eafe, vigour, and habitual fprightliness of the body so much depend. From that degree of irritability which the nerves possess, when in a debilitated state, arise all hysteric, spasmodic, and convulsive symptoms and affections. These may be mitigated or removed by the cold bath; because it greatly affects and alters the state of the nerves; it shakes and animates them, and by its forcible operation overcomes their tendency to preternatural rigidity and other disagreeable sensations. Here then we have two causes, which illustrate the excellent effects of this remedy: there remains, however, a third, more important and powerful, yet to be explained.

The blood, which by external pressure is driven into the internal vessels, extends and enlarges them, without diminishing that contractile force or tendency which is peculiar to every artery. At the moment when the external pressure ceases, all the internal vessels exert their powers of self-contraction more forcibly than usual, as they are more strongly extended, and consequently enabled to exercise a greater force. The blood returned to the cutaneous and muscular vessels, sinds its

refervoirs contracted and invigorated; it flows through muscles, the sibres of which have acquired greater elasticity and power of resistance. It is accelerated in its new motion by these improved sibres and veins, and the result of the collective powers is a fresh impulse and rapidity given to its circulation. Although, at the sirst immersion, the uniform course of it is somewhat interrupted, this temporary stoppage serves afterwards to re-establish and promote it. The blood can now penetrate with ease into the smallest capillary vessels; and it can circulate freely through every part of the animal machine, without affecting or relaxing the solids.*

* Such are the advantages which the theory of bathing holds out. I shall, however, quote a respectable authority, which may be of use to remove some erroneous notions hitherto very prevalent, in the

practice of cold bathing.

"In the earlier flages of exercife, (fays Dr. Currie, of Liverpol,) be fore profuse perspiration has dissipated the heat, and satigue debilitated the living power, nothing is more safe, according to my experence, than the cold bath. This is so true, that I have for some verse contantly directed infirm persons to use such a degree of exercite, before immersion, as may produce some increased action of the value style such as the same produce for law style state, with some increase of heat, and thus secure a sorce of reaction under the shock, which otherwise might not always take place. The popular opinion, that it is safest to go persectly cool into the water, is sounded on erroneous notions, and sometimes productive of injurious consequences. Thus persons heated and beginning to perspire, often think it necessary to wait on the edge of the lath, until they are persectly cooled, and then plunging into the water, r, seel a studen chilliness that is alarming as daugerous. In such cases the injury is generally imputed to going into the water too warm, whereas in truth it arises from going in too cold.

"But though it be perfectly fafe to go into the cold bath in the carlier stages of exercise, nothing is more dangerous than this practice, after exercise has produced profuse perspiration, and terminated in languor and satigue; because in such circumstances the heat is not only suking rapidly, but the system parts more casily with the por-

tion that remains.

"In his Essay on Swimming, FRANKLIN makes the following obfervation:—' During the great heats of Jummer, there is no danger in The healthy and the vigorous, who refort to the cold bath, on account of its cleanling and bracing effects, may continue in it, with fafety, for a confiderable time. But to strengthen and to give elasticity to the folid parts, every thing depends upon the fudden impression of the cold. This primary effect will be weakened or frustrated by remaining in the bath till the water feels warm, whereby the pressing or vibrating action on the nerves at length ceases. The most proper time of bathing is, when the stomach is not employed in digestion; as in the morning or forenoon, or from three to four hours after dinner.

The cold bath, between 65 and 32° of Fahrenheit, is not, strictly speaking, a dietetic

bathing, however warm we may be, in rivers which have been thoroughly warmed by the fun. But to throw ourfelves into cold fpring water, when the body has been beated by exercise in the sun, is an imprudence rollich my prove fatal. I once knew an inflance of four young men, who, bring norked at barveft in the beat of the day, with a view of refreshing t m-Telves, plun ed into a spring of cold water; two died on the spot, a third the next m rning, and the fourth recovered with great difficulty." authority of the American Bacon is of great weight in M dicine, as in every branch of fcience, and particularly in what respects imm rfrom in water; for doubtless he spent more time in this element, than any philosopher of modern days. It may, however, be casily f pposed, that he adopted the commonly received opinion, that the injury arose from the persons in question going in when hot, inst ad of from going in when cooling, after having been heated; to which last circumstance it can hardly be doubted, that the sat. accident he relates was to be imputed."

These remarks are worthy of the learned Dr. Currie;—at the same time, instead of advising any person to use the cold both after exercise, I would certainly prefer the tepid or lukewarm both, both on account of the greater safety attending the use of it, and because it possesses nearly all the advantages of the cold both, without being liable to so many strong objections. Besides, the cold both is altogether improper in a weak state of the lungs, in all complaints of the breatt, in dropsies, in plethoric hab is, and for very corpulent individuals; in all which cases the lukewarm both may, if duly modifications.

ed, produce effects highly beneficial.

remedy;—its effects are not fo much calculated for the healthy and robust, as for the infirm and diseased, under peculiar circumstances. The external use of cold water is of singular benefit, when applied to particular parts of the body, where its use may be much longer continued without danger, and where we may accomplish the intended effects, in a man-

ner, by compulsion and perseverance.

Of all the parts of the body, the head receives most benefit from the affusion of cold water; this is a simple and effectual remedy against too great an impulse of the blood towards the head, where persons are threatened with apoplexy; in diforders of the brain and cranium; in wounds and other complaints, to which the head is subject. In these instances, its effects may be still farther improved by frigorific or cooling falts. The affusion of water upon the abdomen has likewise been employed with great advantage, in cases of obstinate costiveness, affording almost instantaneous relief, when internal remedies have produced no effect. This Thould not, however, induce any person to try that remedy indifcriminately, or without proper advice.

On the contrary, in all those cases where the cold bath might repel certain eruptive humours, which Nature determines towards the surface of the body, it cannot be resorted to without danger. Apoplexies have been the frequenc consequences of an unwary use of the cold bath; more frequent, indeed, than is generally suspected. And yet the popular opinion still prevalent, is, that there can be nobetter practice, than to plunge into the cold bath at all times, and in all states of the body, in order to strengthen the rerves. Children, in particular, are indifcrimentaly remained to it from their infraction is the them to that degree of the like vig we, for which our ancestors were to the That many children, by the daily profess of bothing them in cold water, grow and continue healthy and strong, proves as little, as that many infants become vigorous and robust in the most unwholesome climates, and under the most unfavourable management.—Some think to fortify the body, by the use of the cold batir, against the vicissitudes of the weather; but it can be proved that children, who from their infancy have been bathed in cold water, are as much exposed to coughs and catarrhs, as those who have not been habituated to this -violent practice, provided they have not been mismanaged by effeminating indulgence. In general, all artificial plans of hardening and bracing the bodies of children, are commendable only, when the child shows no strong and lasting aversion to them.

It should be considered that, as the cold bath powerfully contracts the sibres by its frequent use, it imparts to the juvenile body an unnatural degree of solidity and compactness, whereby it too early acquires the properties of an adult. The skin of such children as have been too frequently bathed, is generally much drier and harder than it ought to be at their age. It is a remark of GALEN, that the cold bath does not agree with a growing per-

fon, and he advises young people not to bathe at all till the body be completely formed. Is it not inconsistent, that by cold bathing we expect to bring the body of youth to the vigour of age, and that afterwards, when age approaches, we should wish to render it softer, and restore its energy, by lukewarm bathing? Hence the cold bath, for the purpose of strengthening children, must ever be consid-

ered as a doubtful remedy.

We now proceed to lay down fome rules for the use of the cold bath, in the cases where it may be of service. 1st, Every cold bath applied to the whole body ought to be of short duration; all depends upon the first impresfion the cold makes on the skin and nerves, it being this impression which hardens us against the effects of rough and cold weather:-2d, The head should be always first wetted, either by immersion, or by pouring water upon it, or the application of wet cloths, and then plunging over head into the bath:-3d, The immersion ought always to be sudden, not only because it is less felt than when we enter the bath flowly and timoroufly, but likewise because the effect of the sirst impresfion is uniform all over the body, and the blood in this manner is not driven from the lower to the upper parts. Hence the Shower Bath possesses great advantages, as it pours the water fuddenly upon the whole body, and thus in the most perfect manner fulfils the three rules above specified: -4th, The due temperature of the cold bath can be afcertained only in relation to individual cases: as it

extends from 33 to 56° of Fahrenheit, except in partial bathings, where, as has been already observed, the degree of cold may, and often ought to be, increased by ice, nitre, alum, salt, fal ammoniac, or other artificial means: -5th, Gentle exercise ought to precede the cold both, to produce some reaction of the vascular system in entering into it; for neither complete rest nor violent exercise are proper, previous to the use of this remedy :- 6th, The morning or forenoon is the most proper time for cold bathing, unless it be in a river,-then the afternoon, or towards the evening, when the water has been warmed by the fun, and the dinner has been digested, are the most eligible periods of the day. A light breakfall will not be detrimental before using the bath: -7th, While in the water, we should not remain inactive, but move about, in order to promote the circulation of the blood from the centre of the body to the extremities: -8th, After immersion, the whole body ought to be wiped, as quickly as possible, with a dry and fomewhat rough cloth. Moderate exercise out of doors, if convenient, is proper, and indeed necessary.

To specify the various situations, in which the cold bath may be used with perfect safety and advantage, would lead me too far, and does not belong, strictly speaking, to the subject of this book. I shall, however, enumerate generally certain cases, in which we must absolutely refrain from the cold bath. I. In a general plethora or full habit of body, and in the febrile disposition which attends it; in he-

morrhages or fluxes of blood, and in every kind of inflammation. 2. In conflipations or obstructions of the abdominal intestines. 3. In diseases of the breast, difficult breathing, and short and dry coughs. 4. In an acrimonious state of the sluids, bad colour of the face, dissicult healing of the slesh, and the scurvy, properly so called. 5. In gouty and rheumatic paroxysms. 6. In cutaneous diseases. 7. In a state of pregnancy. And lastly, 8. In a deformed or ill-shaped state of the body, except in some particular cases to be determined

by a physician.

The best method of cold bathing is in the sea or a river. Where, from necessity, it is done in the house, I recommend the Shower Bath, for which a proper apparatus is to be had at the tinman's. Where the faving of expense is an object, it may be effectually supplied by the following easy expedient: Fill a common watering-pot with cold water; let the patient fit down undressed upon a stool, which may be placed in a large tub; and let the hair, if not cut fhort, be fpread over the shoulders as loofely as possible; then pour the water from the pot over the patient's head, face, neck, shoulders, and all parts of the body progressively down to the feet, till the whole has been thoroughly bathed. Let the patient then be rubbed dry, and take gentle exercise, as has been already recommended, until the fenfation of cold be fucceeded by a gentle glow all over him. When we first resort to this kind of bath, it may be used gently, and with water having fome degree of warmth, fo as not to make the shock too great; but, as the patient becomes accustomed to it, the degree of cold may be increased, the water may be allowed to fall from a greater height, and the holes in the pan may be made larger, so as to make the shower heavier. A large sponge may, in some measure, be substituted

for a watering-pot. Although the Shower Bath does not cover the furface of the body fo univerfally as the usual cold baths, this circumstance is rather favourable than otherwise: for those parts, which the water has not touched feel the impression by sympathy, as much as those in actual contact with it. Every drop of water becomes a partial cold bath in miniature, and thus a stronger impression is excited than in any other mode of bathing. The Shower Bath, for the following reasons, possesses advantages superior to all others. 1. The sudden contact of the water, which in the common bath is only momentary, may here be prolonged, repeated, and made flow or quick, or modified at pleasure. 2. The head and breast, which are exposed to some inconvenience and danger in the common bath, are here at once fecured, by receiving the first shock of the water; the blood is consequently impelled to the lower parts of the body; and the patient finds no obstruction in breathing, or undulations of blood towards the head. 3. The heavy preffure on the body occasioned by the weight of the water, and the free circulation of the blood in the parts touched by it, being, for some time at least, interrupted, make the usual way of bathing often more detrimental than useful. The Shower Bath, on the contrary, descends in single drops, which are at once more stimulating and pleasant than the immersion into cold water, and it can be more readily procured, and more easily modified and adapted to the circumstan-

ces of the patient.

I shall conclude this Chapter with some account of what is called the Aerial or Air Bath. This is a late invention, the effects of which have not yet been sufficiently ascertained. Experience informs us, that by expoling the naked body for a fliort time to an agreeable cool, nay to a cold air, we perceive effects somewhat similar to those produced by the cold bath; particularly that of a pleafant fensation of heat diffused over the whole body, after having again dreffed. There is little danger of catching cold upon this occasion: for in a place where we already feel a certain degree of cold in our usual dress, the sensation of it will not be much increased, if we undress altogether. It may also be remarked, that with the whole body naked, we have much less to apprehend from the effects. of cold, than by exposing or keeping one part of it less covered than another.*

Led Monladdo, the author of "Ancient Metaphylics," who do do no May 1793, in his 30th year, till very lately accultomed himfelf to take violent exercife, when quite undressed, in the open air. He also anointed his body, like the ancients, with aromatic oils, especially in certain states of the atmosphere: in the severest weather he never would enter a carriage, which he looked upon as an unjustifiable esseminacy; but annually rode from Edinburgh to Lendon, and took other long journeys on horseback. And this venerabe judge and amiable man found himself, long after the age of 70, as hall, and in many respects as vigorous, as he had been at 30 or 40.

This species of bath certainly deserves farther trials. A spacious apartment, with open windows, may serve every purpose of moving in the free air. And here I would recommend to all who are engaged in sedentary and literary pursuits, to walk with their heads uncovered in an open, and even in the coldest air, as being a simple and excellent means to strengthen the head, and to remove those complaints which arise from intense thought

and close mental application.

To rub the body with woollen cloths, or with foft brushes, is of great advantage, by gently stimulating the fibres, increasing the circulation of the fluids to the external parts, and promoting a free perspiration, together with all the other evacuations. Persons of a delicate habit, of a fedentary life, and those who are liable to fudden twitches of the tendons, cramps, and lameness, may effectually relieve, or rather prevent these complaints, by causing the whole body, particularly the limbs, to be rubbed every morning and evening, for about half an hour, with rough cloths or foft brushes, till the skin becomes red. This friction is still more beneficial to the aged than to the young; and it may in a great meafure produce the falutary effects of bodily exercife.

Frequent cutting the hair is of advantage to the eyes, the ears, and to the whole body. So the daily washing of the head with cold water, is an excellent remedy against periodical head-achs. In coryzas, or defluxions of the humours from the head, and in weak eyes,

the shaving of the head often affords immediate relief; while at the same time it opens the porcs, and promotes perspiration. It is altogether a mistaken idea, that there is a danger of eatching cold from the practice of washing the head, or leaving it exposed to the free air, after having been washed. The more frequently the furface is cleanfed of feurvy and fealy impurities, the more eafy and comfortable we feel. The oftener the hair is cut, the more quickly it grows again; and this eafy operation supplies the place of a constant blister or artificial islue.*

Friction of the foles of the feet is very advantageous; but, on account of the great number of highly fensible nerves in them, such practice must not be carried to excess. A proper degree of warmth and perspiration in the feet is always a favourable fymptom of health: Besides, they should often be bathed in cold, or, still better, in lukewarm water, well rubbed, and the nails cautiously cut. There will then be no danger of the nails growing into the flesh, or of corns or other callosities arising in the feet. All the methods hitherto discovered of extracting corns, afford only

^{*} All fecret compositions or pomatums for making the hair grow long and thick, are little better than fraud and imposition, and gencrally confift of noxious ingredients. In place of them, I recommend a fumple mixture of olive oil and fpirits of rofemary; to which may be added, a few drops of oil of nutmeg. With this mixture let the hair be anointed every night; but fparingly at first.

To change the hair to a darker colour, the liquid remedies fold by the perfumers are generally dangerous, as confifting of lead, antimomy, and other metallic folutions. The only method to be purfued with fafety is, to cut the hair pretty close to the head, and comb it morning and evening with a leaden comb, which simple process cannot injure or check the peripiration of the head.

temperary case; and it is very dangerous to cut them too deep, on account of the many nerves running in every direction of the toes. Easy shoes, frequent bathing the feet in lukewarm water, with a little salt and pot-ashes dissolved in it, and a plaster made of equal parts of Gum Galbanum, Sasson, and Camphor, are the only remedies I can recommend against this troublesome complaint.

CHAP. IV.

Of Dress;—the advantages and disadvantages of the usual mode of Clothing considered, together with proposals for remedying its defects.

In considering the various articles of Dress, attention must be paid both to their fub-stance and form. Our mode of clothing may occasion trouble, disease, and death—1. When we attempt by it to improve some supposed defects of the body, which cannot be done without injury; and, 2. When it consists of improper substances, whether used from necessity, or in compliance with fashion and ca-

price.

To avoid ridicule, we comply with the prevailing fashions of the day; but, if this compliance be prejudical to health, it shows great weakness to allow ourselves to be carried away with the stream; and although a deviation from the mode may, for the moment, excite the ridicule of the thoughtless, yet those who have the boldness to oppose the Tyrant, when his dictatorial mandates are injurious to health, will in the end triumph, and they may themselves have the satisfaction to introduce dresses, at once healthful and elegant. Happily, in this respect, people begin in some degree to think for themselves; that rigid adherence to the mode, which heretofore dreffed both men and women as much in uniform fuits as a regiment of foldiers, does not now difgust us.

The general properties of a good dress are the three following:—1. That it be not so hard and unpliable, as to obstruct the free and easy motion of the joints, and be uncomfortable, either from its weight or tightness:—2. That it preserve the body in that degree of temperature which is most agreeable, as well as most suitable to the different functions and motions in a healthy state;—and, 3. That it do not produce any detrimental effects, by increasing perspiration in an unnecessary degree, or too much absorbing the vapours of the atmosphere.

On the Materials used for Articles of Dress.

THE property of receiving, repelling, and emitting heat and cold, depends not only on the substance from which our dress is made, and its shape or form, but also on the colour. Clothes of a light colour have the least attraction for heat, and therefore are the most proper in hot weather. Substances of a very finooth and flining furface strongly reflect the rays of the fun, which cannot penetrate through them; hence the advantage, in hot climates, of hats covered with oil-skin, particulariy of a green or white colour, of fmooth and thining thoes, glazed gowns, and the like. Dazzling colours are offensive, and a person who fuffers from weak eyes will injure them still more by wearing crimson or scarlet, or being much in company with others thus dreffed. For a fimilar reason, splendid white

dresses, steel buttons, gold and silver lace, and all ornaments of this fort, are detrimental to vision.

Animal Wool produces a moderate warmth, on account of the stimulus and gentle friction it occasions on the skin. By its use, animal electricity is elicited, perspiration promoted, the perspired humours are absorbed, and again easily evaporated, on account of the porous nature of this substance.

Linen Cloth, by diminishing the elasticity of the skin, increases the internal warmth, and at the same time, from its compactness, retains too readily the perspirable humours, and does not part with them so readily as wool. Soiled shirts therefore produce a disagreeable cool-

if made of thick strong cloth, and not regularly changed every day.

Silk occasions a gentle stimulus, but does not sufficiently promote perspiration, though it attracts less humidity from the atmosphere

ing fenfation, and ftop perspiration, especially

than linen.

Oil-skin, or wax-cloth, increases perspiration in an uncommon degree, but does not admit it to evaporate again, and is therefore appli-

cable only in certain difeases.

Cotton stands in the middle between animal wool and linen; it increases warmth and perspiration, imbibes and retains the perspired humours, to the injury of the wearer, and like wool readily attracts infectious matter.

All kinds of Fur are more noxious than useful, both with respect to their structure and constituent parts. They contain many alkaline and oily particles; they are generally too compact and unequal on the furface; they too much stimulate and increase perspiration, by promoting the access of humours to the skin; they do not allow the perspirable matter to escape, soon acquire an intolerable smell, and, more than any other substance, attract and retain contagious effluvia. Experience informs us, that nations who ducks in fur, particularly in hot countries, are frequently exposed to diseases, owing to a want of cleanliness and free perspiration; such are the putrid fevers of Hungary, the plague among the Turks, and the fingular difease of the hair in Poland, called plica polonica, which curls the whole hair into a number of twifts, that have the appearance of fo many greafy strings, and afford a ghaftly spectacle.

We ought, therefore, to choose a dressagreeable to the season and weather, as wellas to the constitution of the body. Woollen clothes are the most proper in spring, autumn, and winter; because they moderately warm the body, do not weaken it by the abstraction of too many exhalations, and have the fewestpoints of contact, or, in other words, do not attach so close to the body, as any other ma-

terials of drefs.

In fummer, most people are accustomed to wear thin clothes, which are scarcely proper in our changeable climate. It is not, in that scason, advisable to take much exercise in thin dresses, particularly in the heat of the day. Nor should we venture to wear such clothes early in the morning, when the air is cool,

and the pores of the skin have been dilated by the warmth of the bed;—but still less in the evening, when the heat of the day has so much opened them, that perspiration may be easily checked, and health materially injured.

In our variable climate, it would be preferable to adopt a species of dress, which is nearly uniform in all seasons; for as thin clothes are more immediately pervaded by heat, during the least exercise, it certainly would be more prudent and rational to wear a dress that is calculated to withstand the effects both of cold and heat. That there is no danger in adopting a general dress for all seasons; that, on the contrary, it is the most beneficial plan of managing the body, with regard to the most important function, namely, that of perspiration, I shall endeavour to prove in the next Section.

On the immediate Covering of the Skin.

The first and principal rule with respect to this subject is, that the covering of the skin ought to be always the same, and not be changed according to the season and the weather. The usual consequence of this change is, in the sirst place, an uneasy and painful sensation. A skin accustomed to sine linen only, cannot endure the sensation occasioned by a coarser kind; and cotton is still more disagreeable, but, most of all, animal wool or slannel. In the next place, to change the dress according to the weather,

occupies more time, and requires more expense, than is convenient to the great mass

of the people.

Nevertheless, there are many who, from mistaken maxims of health, accommodate the covering of their skins to the feafons: they dress themselves in winter in flannel, towards fpring and autumn in cotton, and in fummer in linen; a method as abfurd as it is dangerous. Notwithstanding the dissiculties, which each of these changes must produce, while we undergo this new trial on our skin, we expose ourselves at the same time, in every such change, to all possible dangers arising from cold and repelled perspiration. This custom is the more dangerous, as it is usually practifed by the infirm, the tender, and the aged, who regulate themselves less by the temperature of the weather, than by the days of the almanack, when they are periodically accustomed to change their dreffes.

The question, then, which is the most proper covering of the skin, is easily answered. Animal wool seems to recommend itself to us by the very circumstance, that hair is the general covering of those animals which most resemble man in their structure. If men were habituated to go naked in the colder climates, the human body would, no doubt, also be better covered with hair. Animals, in winter as well as in summer, have the same coat, except that in the coldest season their hair is uniformly somewhat thicker and longer, consequently also warmer than in summer, especially

in the northern countries.

Not only analogy, but experience also proves, that wool worn next the skin has indisputable advantages over all other fubstances. For, 1. Flannel is but a flow conductor of external heat to the body, and it the more easily attracts internal heat, and allows it to evaporate the more readily, as it is more porous than any other texture. 2. A fultry atmosphere is extremely troublesome, particularly where great heat is combined with moisture, the humidity checking perspiration, and at the same time conducting too many aqueous particles to the absorbent vessels from without. Here then flannel is of incomparable fervice, fince it keeps the vessels of the skin constantly open, causes them to perspire freely, and admits but a very finall degree of external moisture.

The principal good effect of flannel, however, confifts in its gentle and beneficial stimulus, or that friction which it occasions on the skin, and by which it opens the pores. We must not imagine, that flannel of itself heats more than linen or cotton; for it is not the heat which occasions inconvenience, but the circumstance of the perspirable matter adhering to the skin. In flannel, we may perspire without danger, and undertake any exercife of the body, without difagreeable fensations; not fo, when linen remains wet on the Ikin. If we take violent exercise in flannel, perspiration is necessarily increased, but the perspired matter is communicated through the flannel to the atmosphere, and the ikin remains dry, warm, and comfortable. If we take the same exercise in linen shirts, perspiration is

indeed also increased, but the perspired matter is not imparted to the atmosphere, but is inspissated in a sluid state, clogs the linen, and remains in contact with the skin.

Another advantage which flannel possesses over linen and cotton is, that people perspiring profusely in flannel shirts, may safely venture into the open air, and will not easily catch cold, because flannel does not absorb the perspired humours. If we do the same in linen shirts, the skin will soon be wetted by perspiration, which will occasion a sensation of coolness and shivering; in most cases a violent cold, and very frequently an inflammation of the lungs, will be the consequence. This danger arises from the sluid matter settling on the skin; and we may be still more severely injured, if we at the same time expose ourselves to the action of the wind, or a current of air.

Numberless writers, both ancient and modern, confirm the good effects of flannel next the skin: of these I shall only quote Count Rumford, who says, in one of his earlier Essays, that he is convinced of the utility of flannel shirts in all seasons; that he has worn them in all climates, in the warmest apartments, and in the most fatiguing exercise, without the least disliculty; that he was relieved, by the use of slannel, from a pain in his breast he had been frequently subject to, and never since knew an hour's illness; and that nothing exceeds the agreeable sensation of this dress, when people have been once accustomed to it.

Indeed after the praises bestowed upon flannel, by so many respectable authorities, and by men who from long experience have ascertained its beneficial essects, it is surprising that any individual, however great his reputation, should be whimsical or hardy enough to dispute its general salubrity, merely with a view to establish a favourite hypothesis.

It has been objected, that flannel worn next the skin is debilitating, because it too much increases perspiration; but this is not founded on truth, since perspiration, as long as the skin remains dry, never can be hurtful, nor immoderate. Such mistaken notions have been propagated, from the circumstance, that flannel is frequently ordered by physicians, to increase perspiration in some diseases, where it is necessary to the recovery of the patient: but the copious perspiration is then the effect of the disease, and not of the flannel.

The uneasy fensation occasioned by flannel is of very short duration. That it may make the skin red and inflamed, if it be too much rubbed and scratched, cannot be denied; but it is a palpable falsity that it produces cutaneous eruptions. It has quite a contrary effect; as it preserves the pores open, increases perspiration, and thus removes the cause of cutaneous diseases, which arise chiefly from a checked and irregular state of excretion by

the pores.

In answer to another objection against the wearing of stannel, it is certain, that a stannel shirt or waistcoat may preserve the body as

clean, and much cleaner, than linen, if as fre-

quently changed.*

Wool, on account of its rough furface, is more calculated to abforb infectious morbid matter, than a more fmooth fubstance; but we have nothing to apprehend from flaunel on the skin, and under the usual dress. I am rather of opinion, that it is a better preventive against contagion than any other; because, while it encourages perspiration, it at the same

* This preliminary condition, I prefume, fufficiently answers the objection of a learned writer, according to whom a flannel drets requires a more frequent change than linen, to promote cleanlines, and confequently would produce a contrary effect among the lower classes of people. Yet, in other respects, I fully agree with the celebrated HUFELAND, who lays down the following conditions and limitations in what relates to the use of flannel:-" Upon the whole, fays he, I am of opinion that it would not be advisable, at least to chidren and young persons, univerfully to adopt a woollen texture for the covering of the skin. It is, however, a falutary dress to those who, in all probability, have commenced the second half of their life; to all cold or phlegmatic temperaments; to all who lead a fedentary life; to individuals fubject to catarrhs, or frequent colds, gout, d'arrhea, and partial congestions of the blood; to all nervous patients and convalescents from severe chronic disorders; to perfons who are too fusceptible of the impressions of the atmosphere; and, lastly, in fach climates and purfaits of life as are exposed to frequent and sudden changes of air.—It is, on the contrary, hartful to all those, without exception, who are already fubject to violent perspiration, cr troubled with cutaneous eruptions, and who cannot afford to change their under drefs as often as is confiftent with cleanlinefs."

Professor Huseland, doubtless, meant to say that the wearing of stannel next the skin is then o by burtful, if none of the conditions before specified reconcile its use; for, even in eases apparently doubtful, the temporary wearing of stannel is not attended with such danger as might perhaps result from neglesting its application. But although the boolviously conductive to realth, the Professor recommends only such a texture of wool, as is sufficiently porous, and neither too rough nor too thick. Coarse weollen slockings in winter, and thin ones in summer, ought in his opinion to be more generally worn. Those persons, lastly, who are in a good state of health, and have no particular reason for wearing stannel, or whose skin is too irritable, may find it, he thinks, beneficial to wear a cloth subtracted of a nixed tex-

ture of cotton and linen.

Medical and Physical Journal: No. I. p. 40 and 41.

eime removes the inhaled poisonous particles, particularly if, in cases of danger, perspiration be increased by other fuitable means. Hence people wearing flannel on their skin, never fuffer from cold. I have been informed, that the manufacturers in the different founderies of Birmingham, as well as at the iron-works of Colcbrook-Dale and Kettley, in the most intense heat, wear no other but flannel shirts; and that without these it would be impossible. to prevent continual colds, and the most fatal diseases. With this beneficent intention, the British foldiers upon the Continent, some years ago, were furnished with flannel waistcoats, by the liberal fubscriptions of individuals, which, I am convinced, faved many lives that must otherwise have fallen victims to the effects of a cold and moist climate.

These advantages strongly recommend the use of flannel to every one anxious to preservehis health, but particularly to those who are exposed to all kinds of weather, as husbandmen, fishermen, mariners, foldiers, and travellers. As flannel is fuitable to all feafons; as it requires no great changes in the under dress; and as it is a tolerable fubflitute for a deficiency of upper drefs; it deserves every attention among those who provide for orphan and poor-houses, as well as for the indigent of evcry description. Many desperate diseases in the legs of the common people, many inflammations of the throat, breast and lungs, might be prevented, and many lives faved, both of children and adults, if flannel were more gencrally worn.

U 2

Those who complain of cold legs and feet, are never comfortable nor healthy; if they could be prevailed upon to wear worsted flockings and flannel drawers, they would acquire a quicker circulation of the blood in the lower extremities, and prevent many troubles and indispositions, from which, without this precaution, they cannot escape. Most valetudinarians and patients flight this advice, because they imagine that the wearing of flannel is attended with uneafy fensations. This idea, however, ought not to prevent them from giving it a fair trial; for the uncomfortable feeling continues only for a few days, as I have myself experienced; and this trisling facrifice cannot be compared with the falutary effects, which flannel next the skin almost uniformly produces. By continuing it fufficiently long, and changing it frequently, the most obstinate gouty and rheumatic complaints have often been removed, and many other imminent dangers averted. Children afflicted with rickets, cannot be better relieved than by a proper diet, and flannel shirts, which may be daily fumigated with amber, petroleum, or other fragrant substances; a process, which has been frequently productive of the most beneficial effects.

Of Stockings.

Cotton flockings, which are fo generally worn at prefent, are highly objectionable.—

There is no part of the human frame, which perspires so much as the feet. The disagreeable sensation cold feet produce is well known; for the connexion between the feet and head, the stomach, the uterus, and many other important parts of the human fystem, is so intimate, that gout, suppression of the critical evacuations, pain in the excretory organs, nay cancer, inflammation of the uterus, and abortion, may be the confequence of cold feet and legs, which are the necessary effects of wearing cotton and filk stockings. Cotton and linen worn next the skin, if once filled with perspirable matter, do not admit any more to pass through them; a glutinous and cooling moisture accumulates, and it is not eafy to keep the feet thoroughly clean in this drefs. Those who alternately wear cotton and worsted stockings, must soon observe the difference in the exhalation and moisture peculiar to each. Cotton, though fomewhat better than linen, is still much inferior to wool, which is alone calculated to abforb and exhale the noxious humours emitted by the

The reciprocal effect of the perspiration of the feet, and of the leather of the shoes, is greater than is commonly believed. Hence those, who wear cotton stockings; ought, from respect to cleanliness, as well as health, to change them according as their exercise

increases perspiration.

Although the feet are the principal fources or conductors of exhalation from the body, little attention has been paid to them, with a

view of promoting this falutary fecretion. Instead of profiting by this hint of nature, mankind have been imprudently and unaccountably fludious to stop that canal; imagining this to be the fafest way of preserving the feet dry, and free from all disagreeable smell. Dry feet are certainly preferable to moist: but the means of promoting perspiration are also the only means capable of keeping the feet dry, and free from any unpleafant fetor. It is also improper and unhealthy to wear any other but woollen gloves, which ought to be worn by all females, who wish to improve the skin of their hands and arms'; no cofinetics or washes are so certain and so powerful in their effects: on the contrary, all external applications, unless assisted by internal remedies, are attended with the politive ruin of skin, bloom, and health.

Persons who have a great tendency to persipire in their seet, and who increase this exudation by much walking or dancing, will no doubt be sensible, that their cotton, thread, or silk stockings, instead of removing the transpired matter, actually absorb it; bring it in contact with the skin; preserve it in a state of heat favourable to putrefaction; and check.

all farther perspiration.

That the feet are more exposed to the effects of cold, and to stagnations of the sluids, than any other part of the body, is unquestionable: 1st, because they are the most remote parts from the heart, and the quickness of the circulation of the blood decreases in proportion to that distance; and 2d, the

blood circulating downwards makes its way to the heart fomewhat flower, on account of its own gravity. By this flowness in the circulation, more watery particles are deposited by the blood. It is therefore necessary to keep the feet somewhat warmer than the rest of the body, in order to encourage the motion of the fluids to the upper parts. Woollen frockings are excellently adapted for that purpose, and they ought to be chosen rather thicker than those flannels used for shirts and drawers. For the fame reason, it is proper to prevent all moisture from without, by means of water-proof shoes, provided with thick cork foles for the winter, or with elastic focks of horse-hair.

The most disagreeable sensation produced by the seet in perspiring, is between the toes: this can only be prevented by wearing stockings made with toes, like the singers of gloves; because these alone can absorb and prevent the viscid and setid particles from settling there. But as this proposal is not likely to meet with the approbation of the votaries of sashion, I shall substitute an easier method of remedying the unpleasant effects of violent perspiration in the seet. A powder of burnt alum will overcome this setor, by neutralizing the acrid particles; and, at the same time, will not obstruct the necessary perspiration.

Of Drefs, as to its Form.

ALL coverings of the head, of whatever kind, produce more mischief than benefit.

The well known and excellent rule of keeping the head cool and the feet warm, is too much neglected, especially by the lower classes of the people in many countries, as in Scotland, Holland, and Germany, and likewife among people of a certain age and description in this country. The Scotch peafant wears his heavy bonnet, the Dutchman his cap, and the Turk his turban, without confidering that fuch heavy loads are stupifying, and that, while no attention is paid to keep their feet warm and dry, their heads are virtually converted into vapor-baths. In all countries, the man who lives at his case, carefully covers his head with a warm night-cap; he spends perhaps one half of the day in this unnatural drefs, and prepares his head for frequent colds, at every fudden change in the atmosphere. Betides, weakness of the head, pains, eruptions, local plethora or fulness of blood, loss of the hair, lethargy, and at length stypor or infanity are often the effects of this imprudence.

In our moderate climate, we might fafely accustom our youth to go with the head uncovered; as Nature has already provided it with hair for that purpose. In very cold and hot countries, however, the head must be

For some years the ladies, instead of those horrid masses of frizzled hair, which used at once to injure their health, and disnigure their faces, happily returned to beautiful and elegant nature; having their hair hanging down in graceful ringlets, while the only artificial covering was a simple turban, or an ornamental bandeau. Of late, however, this tasteful style of decoration has been succeeded by unatural, disgusting, and unhealthful wigs; a fashion probably introduced by some ugly and bald woman, to reduce her gay and beautiful imitators to her own standard of deformity.

flightly covered, to flielter it from cold, or from the ftill more dangerous vertical rays of the fun.

It is an inftance of improvement in the education of children in England, that their tender heads are not fo much shut up in close caps, and sur bonnets, as those upon the Continent. A practice so injudicious and hurtful deserves no imitation; and yet there are advocates for warm night-caps and wigs; they would starve their feet, while the head is enclosed in an artiscial stove, which enseebles their mental faculties, and diminishes their bodily vigour.

New-born children, and those who are most tender, require only an easy and moderately warm covering for the head, and this chiefly during the first weeks, on account of the softness of their cranium, then but imperfectly offisied. Yet such a cap should be loosely tied, that it may not press the head, nor cripple

the muscles of the ears.

That the ear is naturally capable of some motion, is proved by the muscles with which it is provided. Its form, resembling a shell, is admirably adapted to receive and convey sound. In the vain conceit, that a projecting ear, so as the Author of nature has created it, is a deformity, nurses and overwise matrons endeavour to press the child's ear, from its sirst appearance, close to the head. Thus they render the shell of the ear immovable, and diminish the capacity of hearing. A properly-expanded ear not only strengthens the acuteness of hearing, but likewise preserves this

ufeful fense to a great age, when the muscles of the internal organs of hearing become relaxed.

To go with the head uncovered, in funshine, is certainly improper, both for children and adults; but our common black hats are ill calculated to avert the mischief, as they do not reflect the heat, but rather concentrate it in the most fensible manner upon the head. Hats of a white, or any other light colour, made of straw or similar light materials, would be far preferable, particularly for people labouring in the fields, soldiers, and travellers. In very hot weather, a piece of white paper may be fastened with advantage on the crown of the hat.

As the hat ought likewise to shelter the eyes from too vivid a light, the brim should be broad enough to protect them, and the inner side of a green or blue, but not of a black, nor a dazzling colour. From the present mode, however, it appears that both ladies and gentlemen think a brim almost, if not altogether unnecessary, even when the power

of the fun is most oppressive.

Persons suffering from periodical head-achs, or whose heads are otherwise unhealthy, should have their hair cut short. By this petty sacrifice, they will promote the necessary perspiration, the head will remain cool, and the cold bathing of it can be practised with more advantage. In this point of view, wigs cannot be altogether condemned, as long as hair-dressing, artificial braids, and other ornaments, form an essential part of fashionable

drefs. Besides, the wearers of wigs are, in a great measure, exempt from many inconveniences and evils attending the use of powder and pomatum. Lastly, if we must choose one of the two maladies of the times, it is most rational to adopt the least noxious to health: and so far I think a light wig is justly preferable to a head enveloped in an artissical paste of powder and pomatum. Those, however, who are once accustomed to wear a wig, should not upon any account again let their hair grow in order to have it dressed,

pasted, and powdered anew.

With respect to Shirts, the most proper substance having been before investigated, I shall only add, as to their form—that they may be seriously prejudicial to health, if too narrow in the collar, and in the wristbands. I have feen feveral instances of people attacked with shortness of breath and disficulty of speech, from this reason only, because the blood cannot circulate freely, if the neck and wrifts be tied or buttoned up too closely. I was once present where a young man, playing at rackets, was fuddenly seized with an apoplectic sit, the cause of which seemed at first inexplicable. As foon, however, as his shirt-collar, wristbands and garters were loofened, he recovered.

Neckcloths, cravats, ribands, and necklaces of all forts, when they are too tight, stop the access and retreat of the blood to and from the head, occasion accumulations of the blood and other sluids, head-achs, faintings, stupor, apoplexy, corrosive ulcers of the skin,

and innumerable other maladies. All coverings of the neck ought therefore to be constantly worn loofe. People who are liable fore throats, and diseases of the break might gradually accustom themselves, in mold and dry weather, to go with their necks as slightly covered as possible, and if fashion would permit it, to have no other covering but the collar of the shirt. In cold and moist weather, a thin handkerchief might be added. But the modern cravats, filled with a stiffening of cotton or wool, are extremely injurious to the part which they are intended to protect. For, by occasioning too great heat, they render the neck unnaturally sensible to every change of the atmosphere. It is rather furprifing, that from a due sense of their perniciousness, we have rejected all coverings of the neck in children, as being troublesome and useless; and yet, in defiance of reason and experience, we continue to incumber our own necks with fuch bandages.

Necklaces and ribands, likewise, are generally tied so close, as to press with violence on that supposed deformity of the throat, vulgarly called the Adam's apple, which projects less in the semale than in the male sex. These ribands and necklaces, when worn tight, are the more inconvenient and dangerous, if they be narrow and edged. Upon taking them off, which is too frequently neglected at night, they leave an impression on the neck, clearly proving the impediment they are to free muscular action, and what slagnations, pain, and dangerous consequences they

may occasion. The neck and throat, being alternately expanded and contracted, in speaking, chewing, and swallowing, it is the highest degree of imprudence to obstruct its motion, for the sake of appearance, vanity, or fashion.

Equally objectionable are those black stocks, that were formerly much in fashion, and are ftill worn by fome old beaux and military men. The latter indeed deferve our compafsion, from being obliged to wear these uncomfortable collars; but the former ought to confider, that they expose themselves to dangers, increasing as they advance in age, and rendering them every day more liable to apoplexy. I knew a regiment of foldiers on the Continent, whose Colonel was so excessively fond of what he confidered a martial appearance, that he caused his officers and men to have every article of their uniform remarkably tight, particularly the flocks, waistbands, and knee-garters. The confequence was, that in the course of a few months above the half of his regiment became subject to very obstinate cutaneous diseases, and other obstructions, fo that they were unable to perform duty. Other regiments in the vicinity also suffered from this destructive custom; but the proportion of their disabled soldiers was like one to ten in the former. The late Dr. FOTHERGIL afferts, that these tight stocks are productive of apoplexy, if a person look for some time, with his head turned, without moving his body. By this alone, he believes, people have brought on apoplectic fymptoms.

For fuch a turn of the neck, when the body flands fixed, diminishes the diameter of the jugular veins so much, that a proportionate quantity of blood cannot return to them, from the vessels of the head and the brain.

Neckcloths or cravats, loofely tied, and not too thick, are therefore the only proper ones for *Men*; but as to *Women* and *Children*, it cannot be disputed, that they would be bet-

ter without any.

Laced Stays are, among the better ranks of fociety, at prefent out of fashion; since the Grecian form is justly preferred to all artificial shapes. Yet, when we have adopted an useful habit ourselves, it is our duty to recommend it to those also who are still following a destructive practice. And with this intention I cannot but reluctantly observe, that nine tenths of the community still wear these oppressive strait jackets, merely because their mothers and grandmothers have done the same. I shall therefore briefly state a few of the consequences, arising from this unnatural part of female dress, namely, diseases of the breaft, external callositics, and cancer itself; the ribs are compressed; the spine is bent out of its place; the free expansion of the lungs is prevented; hence shortness of breath, indurations and tubercles of the lungs, cramp of the stomach, defective digestion, nausea, irregularities in the fecretory and other organs, and the like: in short, the list of the maladies thus produced is too long to be here detailed; and both married and unmarried ladies, for the fake of compassion, should exert all their influence, to convince the common people of the injuries occasioned by stiff laced stays. If any such part of dress be at all admissible, it ought to consist of soft and pliable materials, such as sine chamois leather, hatter's felt, or, what is still better, the knitted and more elastic texture used for gloves and stockings.

All that has been faid, with regard to laced stays, is also applicable to small waists, and tight coverings of the breast and the abdo-

men.*

Narrow fleeves in gowns and coats, tight wriftbands in fluirts, and bracelets, occasion a swelling of the veins on the back of the hand, rigidity, weakness of nerves, and incapacity of bending the arm. If the arms be in this manner twifted from infancy, their growth and formation are impeded; and it is probably owing to this cause, that we see so many persons with short, thin, and ill-formed arms.

Women suffer much more by this bandage than men, whose arms possess more muscular strength, and have not the interstices of the muscles silled with fat, like the former. In this respect, the modern fashion of tying the sleeves of ladies' gowns close to the elbow, deserves particular censure; as the circulation of the blood, together with the motion of the

^{*} Fashion delights in extremes. No fooner had the fair fex abandoned the unnatural and unhealthful culton of long taper waifts, than they in a manner concealed the waift altogether. Instead of the circumstance the middle of the body, as nature and taste directed, they bound themselves over the breasts,—a custom not less preposterous than injurious to health.

arms, is thus obstructed, and many disagreea ble consequences wantonly induced. Farther, the female arm is naturally somewhat fuller from the shoulder downwards, and again becomes smaller towards the joints of the hand: but in man, it is always more muscular a little below the elbow. From this difference in the structure, it is obvious, that the sleeves in a female dress lie close to the whole arm, while those of a man's coat but partially attach to it.

Many of the remarks already suggested, respecting the form and substance of other parts of dress, are likewise applicable to the article of breeches. If these be made of improper materials, or too tight in the waistband, they must occasion both uneasiness and injury to the body. Yet the ingenious observations, lately published on this subject by Dr. Faust, an eminent physician in Germany, are by no means so conclusive, as to induce us to abandon an article of dress, not only rendered necessary by the laws of decorum, but which, when properly constructed, is even of considerable service; inasmuch as breeches, by their moderate pressure, tend to strengthen the relaxed parts of the body, particularly at a tender age.

The most proper form of this vestment is, upon the whole, that of pantaloons; but they ought to be sufficiently wide, of a thin cooling substance in summer, and of a warm elastic woollen cloth in winter. Tight and contracting leather breeches, purposely contrived to display an elegant shape of the limbs,

are extremely inconvenient, occasion numbness and chilliness all over the hip and thigh, and a painful pressure of the pudenda. Leather is also an improper substance for this part of dress; as, on account of its close texture, it is apt to check infensible perspiration. If the waistband be too strait, the free motion of the internal parts of the abdomen will be obstructed, the absorbent vessels of the intestines prevented from performing their offices, and hypochondriacal complaints be eafily induced. This inconvenience may be entirely avoided, by the use of braces, now almost generally adopted, and which, as they render a tight cincture altogether unnecessary, cannot be too much recommended, both to men and women, for the fake of health as well as comfort.

There are many reasons, which delicacy forbids me to mention, why it would be highly beneficial to the physical and moral condition of females, to wear fome kind of drawers, at least after a certain age. This additional piece of dress would effectually prevent several inconveniencies to which women are subject.-There are other circumstances attending their usual dress, which contribute to bring on a premature fexual impulse, and are apt to induce them to habits equally irregular and injurious to health. This hint cannot be mifunderstood by judicious mothers, and, it is humbly prefumed, will not be totally difregarded;—cfpecially as young females but too readily accustom themselves to sit in an improper posture.

Concerning the clothing of the legs, I must in the first place censure the use of tight garters, particularly in men, to whom they are altogether unnecessary. Whether females can do without them, is fearcely fair to queftion: but if any substitute or contrivance can be adopted in their place, it will amply compenfate any little trouble or inconvenience: the stockings can easily be tied to some tape fastened to the waistband. This apparently trisling improvement is of greater moment, than many are inclined to imagine; for garters are undoubtedly the cause of much mischief, whether tied below or above the knee. The part to which they are applied, acquires an unnatural hardness; they dispose the thighs and legs to dropfy, induce great fatigue in walking, and are very probably the caufe, that certain persons so frequently stumble, fall, and diflocate or break the knee-pan. The great difference in walking, with and without garters, I have myself sufficiently experienced. Many years ago, when in compliance with early habits and prejudices, I was accustomed to the use of garters, I could not walk or ride half a dozen miles without fatigue; which inconvenience I found immediately remedied, on abandoning those improper ligaments.

The advantages of woollen flockings have been already pointed out. Upper stockings of filk, cotton or linen, will be no impediment; and they may be chosen of thicker or thinner quality, according to the weather and feason. But the best stockings may become hurtful, if

too fhort in the feet, and may bring on a spassnodic rigidity, and distortion of the toes. If, on the other hand, the feet of the stockings are too wide, so that they make folds in the shoes, they will injure the skin by their friction, and be attended with painful consequences. The stockings of children ought neither to cover the knees, nor be tied in any other manner, than by fastening them with strings to the waistband; otherwise they will increase the fize of the knees, render them preternaturally thick, and may produce white swellings, and other dangerous maladies.

Boots, if too tight, and made of thick leather, are so injurious to health, and so troublesome in walking, that no reasonable being will be inclined to force his feet and legs into them. The consequences of a practice, as hurtful as it is injudicious, are obvi-

ous from the preceding observations.

The constant use of boots contracts the size of the legs, particularly the calves, as may be daily observed in military men, and the fashionable loungers of Bond-street and Pall-Mall.

I now proceed to the last, but not the least important part of our dress, namely, Shocs. The celebrated Dutch anatomist, Camper, did not consider this subject unworthy of his attention, as he published a particular work, "On the proper Form and Size of Shoes," as late as the year 1781. The shoes ought to be of the fize of the foot; they should be also accommodated to the degree of motion or exercise, and to the nature of the soil and place, in which we wear them; circumstances that

are at present too little attended to. A shoc that is bigger than the foot, prevents a firm step; while one which is too narrow occa. fions pain and troublesome corns. Many volumes have been written on the Art of Shoeing that noble and useful animal, the Horse:—it is considered as a fundamental rule in Farriery, that the shoe must be neither finaller nor larger than the hoof; and yet mankind can submit to screw their feet into a narrower compass than is intended by Nature. How frequently do we finile at the Chinese, who, from a tyrannical custom, fqueeze and compress their feet, that they may remain finall and crippled. Yet thefe feeble Orientals proceed more rationally in this practice, than their European rivals. They begin with it gradually, and from the earliest infancy. We do not think of contracting the fect of our children, till they have almost attained the natural size, and thus endeavour to counteract the progress of Nature, when it is too late to do it with impunity. Who then are the greater flaves of fashion, the Chinese, or their enlightened antipodes?— It is pitiable to see the young and old, of both fexes, advancing into an affembly or ball-room, with the most painful fensations. Without confulting Lavater's Physiognomy, it is easy to discover, by their distorted features and compressed lips, what many whimsical persons fusser from too tight, or, what is still worse, from fhort shoes. Our knees would be more flexible, and our toes more pliable, more useful, and better adapted to perform the various motions of the feet, if they were not continually pressed and palsied by this improper casework. Nature has designed the toes to be as moveable as the singers. Those unfortunate beings, who are born without hands, learn to perform with the toes the most astonishing tasks, to write and cut pens, to sew, to draw; in short, to supply almost completely the want of their hands.

Our feet, no doubt, would be more comfortable, eafy, and useful, if we were not at the greatest pains to deprive them of their elasticity and vigour. The numerous nerves, crossing the feet in every direction, plainly evince that Nature has endowed them with peculiar powers, of which we can scarcely form an adequate conception. The untutored Indian, or the wild African, excels not only the enlightened European, but likewise the lower animals, in running, leaping, and, in short, in swiftness and agility of every kind, where muscular motion is required. Either of them would heartily laugh at us, when we are obliged to employ professional operators for extracting corns, and to contrive ointments and plasters for the cure of those evils, which we have wantonly brought on ourselves.

The judicious Buchan fays: "Almost nine tenths of mankind are troubled with corns; a disease that is seldom or never occasioned but by strait shoes;" and I presume to add, that the remaining tenth part do not envy their fellow-creatures for this modern improvement. Our ancestors, even within

my memory, wore their shoes with broad toes, which showed at once their good sense, and due attention to health and comfort. He who is regardless of the pain and trouble occasioned by warts, excrescences, and callosities of various forms; he who wishes to convert his feet and toes into fo many barometers, to indicate the present state, and to foretel the future changes of the weather, will ever agree with his shoemaker, to save as much leather as possible; and he is fcarcely to be pitied for his imprudence. Such a person will not unfrequently be disappointed in his excursions, when his crippled feet require temporary rest. I am further perfuaded, that fuch cellations of exercise are extremely detrimental to health in general, and that they may be registered among the predifpoling causes of the gout, rheumatism, and dropsy. Many people are thus almost deprived of the use of their legs; and the pain of the more virulent species of corns, as well as of the nails, when grown into the flesh, is excruciating.

For these obvious reasons, the soles of the shoes ought to be sufficiently broad, especially under the toes, where we are accustomed to see them so pointed, that they appear to be intended for weapons of attack or defence. If, for instance, the greatest breadth of the soot be four inches, the shoe should not be three and a half, but rather four and a half inches broad, since the bulk of the soot, and the seam of the leather, require an allowance of half an inch. The soles also ought not to be bent hollow, as is frequently done in wo-

men's shoes; for since the foot is not so confiructed as to present a spherical surface, it is improper to deprive it of that sirm hold, which Nature has given it by a nearly slat form. The foot must necessarily suffer from this ill-contrived shape, which deprives it of its slexion, occasions difficulty in walking, and renders every step unpleasant and unsafe.

In the fame manner as fome perfons strangely endeavour to diminish the breadth of the foot, others are equally diffatisfied with its length. Hence we fee them make use of an instrument, to force their feet into shoes perhaps an inch shorter than is requisite for an eafy motion. This custom is the most destructive of any, and, though not much practifed at prefent, fince a long and narrow pointed shoe is the most fashionable, yet the inconvenience and danger is not thereby removed. Instead of bending the toes with their nails inwards, as was formerly the case with short shoes, we now squeeze them together, and often lay them crossways over one another, so as to carry them about without motion, like a mere infensible mass of matter. Upon striking the foot against a stone, we feel the punishment due to such outrage. Shoes of this kind may be aptly compared to the wooden boxes worn by the Dutch and French peafants, from necessity, in wet feafons, and which admit of quite as much motion as the long and fliarp pointed machines, in which our beaux and belles cranap their feet from choice.

A convenient shoe, therefore, ought to be fomewhat round at the toes, sufficiently long, with thick soles, and the upper leather soft and pliable. If it be desicient in any of these requisites, the skin will be rendered callous; the perspiration indispensable to these parts will be stopped; warts and corns will appear in numbers; the nails will grow into the slesh, and various complicated maladies be produced, which not only affect the seet, but the whole body. Beside these more serious consequences, a person walking with narrow shoes will be much sooner and more sensibly fatigued, than he whose shoes are sufficiently

wide and eafy.

The poor, as well as country people, who wear shoes sufficiently large, have not only a much safer step, but their feet are less subject to the multiplicity of complaints, with which ours are annoyed. Those who, either from inclination or frugality, go barefooted in fummer, have not even to plead the reason of the Ancients, who confidered it as a mark of chaftity; and I cannot help remarking, that it is both indecorous and unwholesome, as well as an injudicious species of economy. The shoe, in our climate and mode of life, is a necessary defence against many accidental injuries, to which the foot is liable; and it is likewife a crime against decency, to expose any part of the human body to dust and mire.

With respect to the fubstance of which shoes should be made, no other general rule can be given, than that it ought to be sufficiently com-

pact, to prevent the water from penetrating it; fo elastic and fost, as to admit an easy motion of the whole foot; and accommodated to the weather, exercise, and soil in which it is used. To those who have not the means or opportunity of procuring the patent water-proof leather, I shall suggest a method of preparing this species of leather, at a very finall expense. One pint of drying oil, two oun es of yellow wax, two ounces of jpirit of turpentine, and one ounce of Burgundy-pitch, are to be carefully melted together, over a flow fire. Those to whom the fmell of pitch and turpentine is unpleafant, may add a few drachms of some cheap essential oil, as of lavender, thyme, and the like. With this composition new shocs or boots are rubbed, either in the fun, or at some distance from a fire, with a sponge or foft brush: this operation is to be repeated as often as they become dry again, until they be fully faturated. In this manner, the leather at length becomes impervious to wet; the shoes or boots made of it last much longer than those made of common leather, acquire fuch foftness and pliability, that they never shrivel nor grow hard and inflexible, and, thus prepared, are the most effectual preservatives against cold and chilblains.

To conclude, I shall only remark, that it is not advisable to change the shoes from one foot to the other. Let us rather tread one of the shoes somewhat crooked, than injure our feet and health, by an adherence to a custom, which has nothing but custom to recommend it. If it be our serious wish to avoid

corns and other painful accidents, to which the rage of fashion subjects the feet of its votaries, we should persuade the shoe-makers to provide us with a particular shoe for each foot; and this can be done only by keeping separate double lasts, for every wearer. Is it not injudicious and absurd, to have both shoes made of the same size and form, when Nature has not formed both feet alike, or at least not in the same direction?

It gives me great fatisfaction to add, that fince the first edition of these Lectures was published, the rational practice of having separate shoes purposely made for each foot, has already been adopted among the more enlightened classes of society. From a full conviction of its great utility, I sincerely wish that it may soon become universal!

CHAP. V.

Of Exercise and Rest; their occasional advantages and disadvatages explained; their manner and limits ascertained; together with directions for regulating both.

OTION, or bodily exercife, is necessary to the preservation of health, which is thereby promoted, while the bounds of moderation are not exceeded. Too violent exercise, and a total want of it, are attended with equal disadvantages. Much also depends on the kind of motion, and the various postures of the body.

The effential advantages of exercife are the following: bodily strength is increased; the circulation of the blood and all other sluids promoted; the necessary secretions and exercitions are duly performed; the whole mass of the blood is cleared and refined, so that it cannot stagnate in the minutest capillary vessels; and if any obstruction should begin to take place, it will be effectually relieved.

That exercise is enjoined by nature, we may learn from the whole structure of the human body, from the number of muscles formed for motion, and from the mechanism in the circulation of the blood itself. There are, indeed, no healthier people than those who have continual strong exercise. Man in a state of health is instinctively induced to muscular exertion; and children that are per-

feetly healthy are constantly running about,

and in almost uninterrupted motion.

But if exercife, either by its violence, or too long duration, exceed the proper limits, it naturally quickens both respiration and the circulation of the blood, which may occasion the bursting of small blood-vessels, miscarriages, inflammations, and collections of blood towards certain parts of the body, such as the heart and the brain. The saline acrimony of the sluids is thus more disengaged; the fat is disfolved; and inslammatory severs, hemorrhages, and palsies, may be the consequences.

Violent exercise is particularly hurtful to those who are unaccustomed to it, or who have committed excesses in drinking, and, what is still worse, in eating more than is necessary: and those whose bodies have not been sufficiently nourished by food and drink, may

also be injured by too much exercise.

The fudden transition from a state of rest, to violent action, is likewise hurtful, and still mode so in hot than in cold weather. After strong emotions of the mind, every species of bodily exercise ought to be avoided, till the tranquillity of mind return with the rest of the body; yet we ought to guard against the effects of cold, as it may prove extremely prejudicial in such a state.

WITH respect to the manner of taking exercise, three principal points are to be attended to:

1. As to the kind of exercise,—the various species of which may be aptly divided into active and passive. The active are of a very diversissed nature; walking, running, leaping, swimming, riding, fencing, the military exercise, different sorts of athletic games, as well as every other kind that requires muscular exertion.—Passive exercise comprises riding in a carriage,

failing, friction, swinging, &c.

The more active species of exercise are beneficial to youth, to those of a middle age, to the robust in general, and particularly to the corpulent, the plethoric, and those whose evacuations are not in due proportion to their supplies. The passive kinds of exercise, on the contrary, are better suited to infants, to old, dry, and emaciated persons, to the delicate and debilitated, and particularly to the

afthmatic and confumptive.

2. As to the time in which exercise is most proper to be taken—this depends on so great a variety of concurrent circumstances, that the rules by which it may be regulated, cannot be universal, and must therefore be collected from the preceding observations on the properties and effects of Air, Food, Drink, and so forth. Other particulars, such as relate to greater or less degrees of satigue attending the different species of exercise, and the utility of it, in certain states of the mind and body, must determine this, as well as

3. The duration of it;—for it is almost impossible to lay down positive rules, how long every individual, in every particular situation, may continue a certain species of exercise, so as to derive advantage. These rules, as far as they can be established, may be collected from the subsequent remarks, and then applied to the particular kinds of exercise, by which we may be benefited in different cases and situations.

It is necessary sirst to observe, that any kind of exercise which we are accustomed to take, with a view to brace the body, is far preferable to an unusual one, which may be attended with a contrary effect. We ought always to begin gently, and to finish gradually, never abruptly. Exercise in the open air has great advantages over that in houses and close apartments. Besides, strong bodily exertions, such as dancing, fencing, turning, and the like, if practised in small and confined places, on account of the increased perspiration, soon vitiate the air, and render it unsit for breathing.

If we take exercise for the sake of health, we ought to employ ourselves during that time with some agreeable object, and not perform any labour nor seriously occupy the mind. Hence certain kinds of exercise cannot be unconditionally recommended to every individual, as means conducive to health; though they should of themselves be proper, and in other respects agree with the constitution. He who forces himself to any exercise, or performs it with reluctance, will thence derive more injury than benefit: motions or

talks, therefore, which we impose upon ourfelves, as recreations after work, or after sitting and long thinking, ought to be strictly

relaxations, not toilsome exertions.

Perions of an active mind find a species of relaxation, and even satisfaction, in a change of their pursuits, and particularly in the transition from hard and difficult, to more pleasant and easy avocations. To such individuals any exercise is frequently of great advantage, especially if it answer, or appear to them to be conducive to any useful purpose. To one who has habituated himself to grave and serious pursuits, it should not be recommended to join in amusements requiring bodily exertion, and attended with diffatisfaction and irksomeness; for his health will not be improved by exercise, at once unusual and unpleasant.

To continue exercise until a profuse perspiration, or a great lassitude, take place, cannot be wholesome. In the forenoon, when the stomach is empty, or at least, not too much distended, muscular motion is both most agreeable and healthful; it strengthens digestion, and heats the body less than with a full stomach. A good appetite after it, is a proof that it has not been carried to excess. But it is not advisable to take violent exercise immediately before a meal; as this might occasion a desiciency of those humours, which are necessary to promote digestion. If we sit down to a substantial dinner or supper, immediately after a fatiguing walk, when the blood is heated, and the body is in a state of perspi-

ration, the worst consequences may ensue, especially if we begin with the most cooling dishes, or with salad, or a glass of cold drink.

Exercise is likewise hurtful directly after meals; fince it obstructs digestion, and propels those fluids too much to the furface of the body, which are defigned for the ftomach, to promote the folution of food, and without which many crude and undigefted particles are forced to enter, and to mix with the blood. The old rule of the Salernitan School, " Post canam stabis, seu passus mille meabis," (i. e. after supper stand, or walk a mile) is as frivolous as it is abfurd; for experience fusficiently informs us, that most perfons, particularly the nervous and irritable, are liable to the heartburn, eructations, and even vomiting, when they are obliged to move about or to take any exercise immediately after meals. The inflinct of the lower animals alfo contradicts this rule; because the wildest creatures are inclined to rest after food.

Persons who are under the necessity of moving immediately after their meals, or who have no other spare time for walking, must endeavour to overcome these inconveniencies by custom, and a more rigid temperance: they should first take the most gentle kind of exercise, and gradually increase it; and, as the late hours of dining, now so generally in fashion, have in a manner abolished heavy suppers, a moderate walk after a slight evening's repast cannot be injurious. But at all events, fatiguing exercise, after a full meal, should be delayed till the stomach has digest-

ed and affimilated the food, which generally takes place in the third or fourth hour after eating. The most proper occupations after dinner, are such as can be performed without trouble, or great efforts of reslection and bodily exertion, and such as afford a kind of amusement.

Walking, the most falutary and natural exercise, is in the power of every body; and we can adapt its degree and duration to the various circumstances of health. By this exercise, the appetite and perspiration are promoted; the body is kept in a proper temperament; the mind is enlivened; the motion of the lungs is facilitated; and the rigidity and contraction of the legs, arising from too much sitting, is relieved. The most obstinate diseases, and the most troublesome hysteric and hypochondriacal complaints, have been frequently cured by perseverance in walking.

The most proper walk for health, is in an agreeable country, in a healthy, pure, dry air, amidst focial and cheerful conversations, in a mild funshiny day, whether in spring, autumn or winter; in the summer mornings and afternoons, but by no means in the oppressive heat of the sun. To walk in towns, although it gives exercise, is less conducive to health; because the atmosphere is generally filled with vapours arising from impure exhalations.

Those who are not hardened against the vicisitudes of the weather, must avoid not only hail and rain, but also the cold mornings and evenings, and ought, therefore, in rough and moist cold weather, rather to take exercise

within the house, but without preventing the access of air. Violent wind should also be avoided; and if we are obliged to face it, we ought not to walk too fast, particularly in winter, when the small porces of the skin are compressed by the air.

In walking, the proper choice of places is a matter of much importance. Marihy and damp fields should be avoided; and in autumn, when the foliage is decaying, it is not advisable to choose woods, groves, and damp meadows, for our pleasure-walks. In summer, on the contrary, a walk in the forests or meadows is both agreeable and healthful. Hills and elevated situations deserve particularly to be visited, not only on account of the purer air we breathe, but also of the body enjoying a variety of exercise, in ascending and descending.

The inhabitants of towns require longer walks for the prefervation of their health than country people. The latter, even with less exercise, derive vigour of body and serenity of mind, from a purer air, and more simple manners. Regular and daily walking, therefore, cannot be too much recommended to the citizen, who in the present age is so much harassed with nervous and hypochondriacal complaints; but, though this be an useful and excellent species of exercise, yet some rules ought to be observed, if we expect to derive from it the wished-for advantages.

1. We should contrive to procure as much pleasure and recreation after serious occupa-

tions, as is possible and consistent with our situation in life.

2. To read during a walk, whether the fubject be of a grave or amuling nature, is a custom improper in itself, and detrimental to the eyes, besides the danger it occasions of falling: this practice not only deprives a perfon of the principal advantages of a walk, but people easily accustom themselves to an unsafe and ungraceful manner of carrying the body. It is attended with the worst consequences to the eyes, because the focus is continually shifted, and the retina is thus excessively farigued.

3. We should not frequent the same, perhaps often a dull and unvaried walk, though most convenient. It is better to change the walk occasionally, and gradually to extend the distance. The most agreeable prospects should be chosen for variety; otherwise the perpetually uniform walk will excite melancholy and unpleasant sensations, as much as the closet or

the study.

4. We ought to accustom ourselves to a steady and regular, but not a quick pace.

5. An agreeable companion contributes much to ferenity of mind: but let us rather go alone, than in dull or frivolous company, if we at all possess the art of profiting by solitude.

6. In the choice of our companions, we should attend not only to congeniality of character and taste, but should also, in this exercise, associate with those whose pace accords with ours; for if the heavy and corpulent man make a lean and light-footed person

Y

the companion of his walks, he will remain behind, or be overheated and fatigued, if he endeavour to keep pace with his partner, who must likewise suffer from the constraint of flower motion.

7. Some people cannot speak or converse in walking, without frequent stops, and thus make little progress. From this singularity, they are generally much satigued at their return, without having reaped any benefit from their exercise.

Running not only fliakes the body with greater violence than walking, but it heats the head and face, and too much quickens the circulation of the fluids. Soon after a meal, it prevents digestion, mixes the pure sluids with the impure, and obstructs the secretion of humours. If long continued, it is hurtful to every one, particularly to those unaccustomed to it, to the plethoric, to those subject to hemorrhages, gravelly complaints, and frequent nervous head-ach, and to fedentary perfons employed in mental labour. To run up a hill, too much fatigues and strains the muscles; and to run against the wind, produces giddiness in the most robust, and makes them liable to various accidents, that may be attended with danger.

Dancing, confidered in itself, and under proper limitations, is an admirable exercise, especially in winter, when the heavy atmosphere, much rest, and sitting, render the blood thick, and dispose persons to hypochondriass. Moderate dances have every advantage of a gentle exercise, besides the beneficial essects

produced on the mind by cheerful company and music. On the other hand, the more violent dances may be, and frequently are, attended with the most pernicious effects. The exertion of fo many muscles, the quick inspiration of a warm atmosphere in a crowded affembly, impel the blood to circulate with a rapidity equal to that in the hot stage of a fever, and propel it to the head and breaft, fo that the veffels feldom possess a sufficient power of resistance. If we add to this, the effect of heating liquors, of too fudden an access of the cold air, fo eagerly courted, of exposing the face, head and breast, suddenly to its influence, together with the imprudent use of cooling drink, and ice itself, we can no longer be surprised, that spitting of blood, consumption of the lungs, and inflammatory diforders, are the frequent consequences of such exceffes.

This violent species of exercise is particularly dangerous to females; and the use of fans, in order to cool themselves, and thus check perspiration, (which is wisely designed by nature to produce the same effect, in a more salutary degree, if not wantonly repelled) is extremely imprudent. Delicate persons ought, for their own sakes, to join in no other but the shorter and less satisfuing dances, especially in summer.

A dancing-room ought to be cool, but without admitting currents of air, and without too much smoke from candles. It would be advisable for the whole company, after dancing is over, and before they venture into the open air, to change their linen, and aftere wards to wait a quarter or half an hour before they return home. During that time, they may be refreshed by tea, and thus encounter the open air without danger. Every dancing assembly ought to conclude with minuets. Persons of an indisposed and debilitated body, such as the consumptive, those troubled with ruptures, gravelly and similar complaints, should not attempt to dance. Lastly, this exercise is hurtful to every person in the hot and sultry days of summer, when nature renders cooling drink indispensable, and when we are much inclined to perspire,

without any additional inducement.

Riding in carriages is an exercise the more conducive to health, that the gentle jolts tend to resolve stagnations in the intestines of hypochondriacs, corpulent people, convalescents, and the confumptive. But, if the motion of the carriage be too rapid, it is hurtful, as it not only accelerates perspiration before the matter of it is properly prepared, but also injures the folid parts, especially the kidneys, generates congestions of the blood towards the head, and consequently head-ach, giddiness, comiting, and obstructions. If, however, we with to derive all the good effects from riding in a carriage, the body of it ought not to be too nicely fuspended in straps and springs, nor should the motion be too flow. One of the windows, at least, ought to be kept open, that the perspiration and breath of several persons, inclosed in so narrow a place, may not too much vitiate the air.

The infirm, who cannot enjoy the free air in bad weather, should take exercise upon rocking horses, or similar contrivances, in halls and spacious apartments, while the upper part of the windows is kept open, guarding, however, against a current of air. Lastly, the furious driving in open carriages, in sultry weather, may be indeed pleasant, on account of the agreeable current of air; but it may also become dangerous to persons subject to violent perspiration.

Leaping, fencing, the fashionable military exercise, and manœuvring with horses, are violent kinds of exercise, which cannot be recommended to those who are not in a perfect state of health, or to the corpulent and plethoric, whose blood-vessels may be so overstrained as to burst, by motions which require the muscular exertion of the whole body.

To those who are otherwise healthy, but cannot afford to take fufficient exercise, either by their particular situation in life, or from want of time, I would recommend a new species, which, in its falutary effects on the whole body, is equal if not superior to any other. It simply consists in moving the whole body, in the middle of a room, (and, if convenient, with open windows) and let the operator, while he inclines forward upon his toes, raife his arms, and drop them with the alternate motion backward on his heels. Thus the whole muscular system will be duly exercised, without confining the motion to one particular part. This is even preferable to the dumb-bells, which, like every other species of

partial exercise, if persevered in, are so far objectionable, as they require the uncommon exertion of certain muscles, while the due and uniform circulation of the blood to those parts is disturbed, to the detriment of others which are at rest.

To persons who are deprived of the use of their limbs, and are weak and delicate, the motion of a sedan chair is of great benefit, if it be continued for a sufficient time; for it disposes the body to a free perspiration. Of the same nature is the sailing in barges or

boats, either on lakes or rivers.

A much more active kind of bodily motion is produced by fhort voyages at fea. Those who are unaccustomed to it, generally experience giddiness of the head, nausea, and vomiting: hence it is beneficial to an impure stomach. To confumptive patients it frequently is the last resource; but it is wrong to delay it, till all other remedies have failed. For it is not in the last stage of consumption, when the lungs are already ulcerated, or when an abfcefs has already burft in the thorax, and the ichorous matter has been communicated to the blood, that we can expect any benefit from voyages. The changes of scene and climate, indeed, powerfully co-operate in effecting changes in the human fystem; but, if the difease has preyed too much on the vitals of a patient, or if he is spitting blood, the motion of the vessel mu't necessarily prove injurious. On the other hand, the debilitated, the nervous, and particularly the hypochondriac, cannot refort to a better remedy

than a short voyage.

Riding on horsiback is, in a certain respect, an excellent medical remedy, by which all the muscles, from the toes to the head, are in reciprocal motion, and which manifests its principal effects on the intestines of the abdomen. It clears the intestinal canal, promotes the evacuation of crude substances, strengthens the stomach and bowels, improves digestion, prevents or resolves incipient obstructions, and facilitates the perspiration of the whole body. To the hypochondriac it is an inestimable remedy; but, if the obstructions should be too far advanced, riding ought either not to be attempted at all, or practifed in as flow a pace as the horse can walk. In short, it is to be undertaken with the fame precaution as failing, in those stages of consumption which admit of these remedies.

Farther, riding is not advisable in cases of hemorrhoids, ruptures, and gravel. The seeble and relaxed ought to begin with a gentle pace, and to increase it gradually; for a moderate trot is the proper medicinal mode of riding: and, if they expect to derive real advantage from riding on horseback, they must neither trot too fast, nor make use of a heavy and jolting horse. Such patients as are unaccustomed to this exercise, particularly hypochondriacs, generally ride with great timidity. Their lives are, as it were, in continual danger; by the awkward posture of their bodies on horseback, they are frequently hurt in parts accessible to injuries; stitches in the

fide, congestions of blood in the head, and violent perspiration, counterbalance every advantage received from their excursions. To most of these patients, if they can assord it, the riding-school cannot fail to be extremely useful; for the regular manner of training the horses there, their uniform and steady motion, the attention paid to the proper pofture of the rider, by keeping his breast and abdomen erect, and the legs properly extended; all are circumstances very favourable to the patient and convalescent. But, even here. it is the moderate kind of exercise only, that promises real benefit in a medicinal sense;continued furious driving and hard trotting are always extremely dangerous.

For fimilar reasons, riding on horseback, as well as in carriages, immediately after a meal, is still more dangerous than walking. The most proper time for riding is the morning, when the stomach is empty. It should, however, not be long continued; one hour, in general, is quite sufficient; and in this respect, riding is preferable to any other exercise, as it can be practised by persons, whose business does not permit them to devote much of their

time to that purpose.

Swimming is likewife an useful exercise, which at the same time has the additional advantage of a cold bath. The motions and muscular exertions, which it requires, increase its utility: some rules and precautions, however, must be attended to. They have been stated at considerable length in CHAP. III. "On the use of Baths." I shall, therefore,

at prefent only remark, that we should not enter with the feet, but with the head, into a cold bath; that the body should be neither too warm nor too cold in applying this bath; and that we should not choose dangerous rivers, or ponds, nor enter the water before the rays of the sun have in some degree warmed it, and rendered it more temperate. The sensation produced by cold water is indeed less to be apprehended, than the consequences arising from imprudently plunging into it, when the body is either too much cooled or heated.

Playing at Hand-ball, Cricket, and the like, have a more powerful effect on the muscles than the abdomen; and are therefore, in one respect, unavailing to sedentary people, and on the other hand unnecessarily fatiguing. Caroussels, or riding on machines in a circle, are movements which require too much mufcular exertion of the debilitated, whose strength admits only of a moderate exercise. These, as well as fivinging machines, and the lately contrived fwinging cars, moving on a wheel with perpendicular pivots, are the leaft proper for those who are inclined to giddiness, and nervous symptoms in general, on account of the fear, and fometimes the dangerous accidents attending them. But, at the fame time, both species of exercise are extremely favourable in fuch states of health, as require an uniform and gentle motion of the whole body, in the pure and open air, particularly in the high fwinging cars, which are well calculated for that purpofe.

Speaking is one of the most healthful and necessary species of exercise; and, without any ludicrous idea, I may affert, that this practice is particularly falutary to the female fex, who are more confined at home than men. Here, however, as in other cases, excess is prejudicial. Loud reading and speaking are of fingular advantage to literary men, affording them good fubflitutes for other kinds of exercise, for which they seldom have sufficient leifure or opportunities. It is to this cause we may justly ascribe the longevity of many schoolmasters, and teachers in univerfities, who, notwithstanding their sedentary employments, and the vitiated air which they daily breathe in school-rooms, attain to a long and healthy life. To speak very loud, and to exercise the voice immediately after a meal, is pernicious to the lungs, as well as to the organs of digestion.

Singing promotes the lively circulation of the blood through the lungs, and all parts of the body; the lungs, as well as the abdominal intestines, are shaken by the vibrating motion of the air, in a manner very conducive to their falubrity. The phlegm, and other noxious matter, collected about the pulmonary vessels, are thereby resolved and carried away, so that they cannot mix with the blood, and the most dangerous stagnations in the smaller vessels are thus prevented: the blood is uniformly distributed and driven to the larger veins and arteries. For the same law of nature, by which river-water is preserved sweet and fresh, while that of pools and ditches stag-

nates and putrifies, is also fully applicable here. The air inhaled in finging is of similar service to us, as the current to the water: perspiration is thereby promoted, and the mind is enlivened with the body. Those sedentary artificers or mechanics, who from habit almost constantly sing at their work, unintentionally contribute much to the preservation of their health.

All Wind Instruments are more or less hurtful; for, as much air is thereby introduced into the lungs, and as it is but gradually and partially emitted, that organ foon becomes debilitated. Hence persons of weak lungs, who are very fond of playing the flute, hautboy, or French horn, are frequently afflicted with spitting of blood, cough, shortness of breath, and pulmonary confumption. Bcfides, blowing checks the circulation of the blood through the lungs, accumulates it towards the head, and disposes such mulicians to apoplexy. By the violent expulsion of the air, the abdominal muscles are contracted, all the parts of the abdomen are compressed, the circulation of the fluids is retarded, and many unpleasant and frequently fatal consequences are induced.

There are other kinds of mufical instruments, which, in a dietetical view, deserve to be condemned. Such is the Harmonica, which, by the rotation of the glasses on the singers, (a kind of negative electricity) induces a great degree of nervous weakness. And this effect is much accelerated by the acute and vibrating sounds of this instrument, by which the

organs of hearing are intenfely affected. Perhaps all stringed instruments, which are played by the touch of the fingers, fuch as the harp, the guitar, and the violin, produce a fimilar effect on the nervous system; especially if it be true, that the papillae, or the points of the fingers, are the firongest conductors of the supposed nervous sluid. It is at least probable, that to be able to play on fuch instruments, with expression, requires a more than common fensibility of the nerves, which indeed may be fometimes artificially acquired, but to the detriment of health. For it cannot be doubted, that a local excitement of irritability may be gradually propagated over the whole nervous fystem; and that, from raising some parts of the body to a preternatural state of sensibility, the common character of those who are called Virtuoli, is generally marked with nervous debility. Every body knows in how extraordinary a manner music may influence the mind; that the passions of persons of sensibility may be most effectually roused and allayed by it; nay, that in some individuals, every feeling of the mind can be affected at pleasure, by the various modifications of harmony. As, therefore, fadness, grief, and other depressing passions, may be alleviated by appropriate music, it is an excrcife deserving every commendation. Yet we must neither expect to cure by it diseases of the mind, nor their concomitant bodily diforders: this is beyond the power of music, which acts as a palliative only, or as a nervous stimulus, the effect of which is instantaneous, but of fhort duration. For, as foon as the exciting cause ceases, it is succeeded by an uncomfortable sensation of debility and relaxation. It is even probable, that music, like all other anodyne and soothing remedies, may in the end increase the disposition to nervous weakness, by its too frequent repetition.

Lastly, the posture of the body, in practifing music, also deserves attention; as the breast and abdomen may be compressed by stooping, so as to cause very serious complaints; and as the eyes may be injured by reading the notes, at too great or short a distance, especially for the double keys of the harp and harpsichord: indeed, reading music is in general more satiguing to the eyes, than

any other kind of exertion.

Triction of the body, which can be performed either by the naked hand, a piece of flannel, or still better by a flesh-brush, is one of the most gentle and useful species of exercise. The whole body may be subjected to this mild operation, but principally the abdomen, the spine, the arms, and legs. It clears the skin, resolves stagnating humours, promotes perspiration, strengthens the sibres, and increases the warmth and energy of the whole system. In rheumatism, gout, palsy, and green-sickness, it is an excellent remedy.

Daily friction of the whole body was with the ancients, and still is in the East Indies, considered one of the most indispensable requisites of a people, who by their indolent manner of life seem to have adopted it, more with a view of indulging in sensual pleasures, than

Z.

as the means of preserving health. It is, however, one of the most falutary expedients, by which the whole body receives nearly as much benefit as from a tepid bath, and which, as being in the power of every person, ought to be more frequently and more generally used. To the sedentary, the hypochondriac, and persons troubled with indigestion, who cannot afford leifure to take fufficient exercife, the daily friction of the belly, in particular, cannot be too much recommended as a fubstitute for other means, in order to diffolve pituitous stagnations, which may be forming in the abdomen, and to re-invigorate the veffels. And though it be not attended with all the advantages enjoyed from exercise in the open air, it still produces a powerful effect on the organs of digestion; for the moderate exercise of a whole day will scarcely invigorate the abdominal vessels, and particularly the stomach, so much as the friction of these parts, continued for half an hour. But, if it be intended for these beneficial purposes, it should be performed in the morning, on an empty stomach, or in bed before we rife, gently and steadily, in a circular direction, and at least for five or ten minutes at a time.

In a weak state of the abdomen, and the nerves in general, we may derive still more salutary effects from friction, if the stomach and the whole abdomen be rubbed every morning, and at night, before going to bed, with a sponge, or a piece of slannel dipped in cold water. This possesses still greater advantages over internal medicines, because it can

be fafely employed, even in cases where the alimentary canal, from its obstructed state, scarcely admits of any other remedies, while friction, and the affusion of cold water, generally relieve these obstructions, and even habitual costiveness.

Motion or exercife ought to be continued only till we feel an agreeable lassitude, and a sensible degree of perspiration. If it be carried farther, it weakens instead of strengthening the body, and leaves behind disagreeable consequences to the lungs, silled with heated blood. Even the robust man will experience some, though less unpleasant effects than the debilitated, if he has committed an excess of this nature.

After having taken exercife, we should not venture to rest in a cool place, nor upon a green plot; still less should we expose ourselves to a current of air; but rather frequent a place warmed by the mild rays of the sun in summer, or a moderately warm apartment in winter, so that the sudden change of temperature may not injure us, by suppressing perspiration.

For the fame reasons, the thirst we generally feel after exercise, ought not to be instantly satisfied by cooling drink. It is however allowable to drink some warm or diluent liquors, if we cannot wait till the natural warmth be restored. The late Dr. Fothergill very properly advised, that people in a state of perspiration should, to avoid all danger, eat a mouthful of bread, with a little salt, and thus gain time, till the blood and the liquox

to be drunk had acquired a more equal teniperature. A finall quantity of vinegar, or the juice of lemons in water, is well calculated to quench thirst, and at the same time to promote perspiration. Travellers on foot ought to be upon their guard against too much drink; for, the more liquids they take, the more they will perspire, and the greater will be the subsequent relaxation and danger of cathing cold, when their clothes are faturated with perspirable matter. They should also abstain from drink productive of a laxative effect, which would cause debility, and even faintings. The most suitable of all substances to mix with water, is the pure or effential acid of tartar, with a fmall quantity of fugar. This affords a cooling and refreshing beverage, without relaxing the bowels, like lemonade. Perfons with whom vitriolic acid agrees, may take a tea-spoonful of a mixture, consisting of fix or eight parts of spirits of wine, and one part of vitriolic acid, to a pint of water. A beverage made of a weak acidulated wine and water is cooling and strengthening. In the very cold weather of winter, people ought to avoid all heating liquors, fuch as ardent spirits and strong wines. Warm diluents, such as tea and coffee, are equally improper, and a poor protection against cold; for their warming property is of short duration; they are productive of debility, a more torpid circulation of the blood, and consequently of an increase of cold. It is much better to eat previously some solid meat, by which the digestive organs may be exercised, such as cold animal food and bread, and to drink after it fome bitter ale or beer. On the other hand, when we fuffer from intense cold, or have been exposed to the wind and weather, a few cups of firong tea, with plenty of cream and fugar, is then the best and fafest refreshment: and it is equally invigorating in summer after extreme heat and fatigue. Feeble individuals, whose stomachs generate much acid, and who are frequently troubled on their journies with a fudden voracious appetite, are liable to the most painful attacks of weakness on the road, and on that account they ought always to be provided with some kind of solid food in their excursions. Such persons should carefully abstain from the use of wine, brandy, or other heating and stimulating cordials, while travelling, especially in the morning they might with more advantage eat some bread and butter, warm or buttered ale, frong broth, gruel, or the like nourishing. substances.

We are now to confider the consequences arising from the want of exercise. This, indeed, is still more debilitating than too violent motion. The solid parts of the human frame are relaxed by it; the circulation of the sluids is retarded; they gradually stagnate in the smaller capillary vessels; the secretions are diminished; and abundance of moisture or sat is generated, which renders the body, as well as the mind, more indolent and lifeless:
—relaxation of the muscles, obstructions of the intestines, hemorrhoids, apoplectic sits, various species of dropsy, and at length a pre-

Z 2

mature death, are the fad confequences. Men of letters are the most unhealthy of all human beings, because their bodies have scarcely any other exercise but the imperceptible motion of the arms. Want of appetite, flatulency, anxiety, at one time obstructions, at another diarrhœa, and the most diversissed nervous fymptoms, are their attendants. Sleep is beyond their reach; a thousand tormenting inconveniencies, hypochondriasis, and at length a complete state of melancholy, is too frequently their lot. Temperance alone will not remedy all these evils; for since we cannot remain vigorous and healthy for two days together, with the same mass of blood, a new access of the purest and most subtle parts of our fluids must daily support the nervous system, in order to preferve its regular functions. If this be not continually restored, weakness and relaxation of body and mind are the inevitable confequences; with this difference only, that in a state of debility, from too much bodily exercise, the thick and coarse particles of the fluids are carried into circulation with the others, and the next meal, or the first sleep after it, very soon supplies the deficiency: in mental labour, on the contrary, digestion is interrupted, the crude and viscid parts of food remain unaffimilated, and the body is prevented from receiving its proper nourishment. In like manner, the sedentary mechanics and artificers are affected; particularly shoe-makers, taylors, and weavers. They experience hardships similar to those, to which men of letters are subject; and it has

been frequently observed, that they are very liable to diseases of the mind, and especially

to religious fanaticism.

Standing, though useful as a change after long fitting, is apt to occasion accumulations of blood, or rather of the serous part of it, in the lower extremities. Swelled legs are therefore common among printers. It is a posture little calculated to relieve the studious, and the body is at the same time more fatigued by standing than sitting. If we sit much, we must attend to the two following rules:. 1. that no part of the body be compressed: and 2. that it be not too long continued at one time. The common manner of fitting; with the head reclined, is extremely pernicious; for the circulation of the fluids in the abdomen is thus checked; the intestines are compressed, and the vessels of the breast contracted. The head also suffers by bending it too much forward; as the blood is thereby. impelled to circulate towards it more copioully than is confistent with health. The studious, especially, would do well, not to perform all their avocations in a fedentary posture, but occasionally to relieve at once their body and mind, by flanding, or walking about the room. The mode of litting ought also to be made as convenient as possible, so that both the body and head may be kept in an almost perpendicular posture; that the breast and abdomen may not be obstructed in their alternate expansion; and lastly, that the arms and legs may not be held in a crooked and unnatural position: all this should be

particularly attended to, by those who teach children to read and write. The pressure of the abdominal muscles may in a great measure be prevented by high tables and desks, and by raised stools or chairs, upon which a

person rather stands than sits.

To lie or rest horizontally is attended with a cessation of all exercise. If the head be placed low, and this too long continued, there may arise head-ach, by the increased pressure of the blood on the brain. Here, likewise, a frequent change of posture is necessary, in order to obstruct none of the bodily functions, and to prevent the stagnation of humours.

Finally, the faculties of the mind deserve no

less attention than those of the body.

Alternate changes of tranquillity and activity are equally beneficial to the mind, as rest and exercise to the body. Too long continued, too frequent, and too profound reflections, are alike injurious to both. The fame powers are diminished here as in bodily labour, and in a still greater proportion; for muscular exertions, though fatiguing, are reproductive of new vigour. This may indeed be also applied to mental labour, by which the mind improves in capacity, but the body is a fufferer from every unufual exertion of the mind; and, with the body, the mind by degrees also becomes diseased:-in profound meditations the vital spirits are, as it were, withdrawn from the organs of fense; the body is for the time almost deprived of sensation; and we frequently become in a manner

absent. Reslection always directed to one object, not only debilitates, but also suppresses the other faculties of the mind, and does not permit it to deviate from its favourite pursuit. Thus we sometimes see melancholy, nay madness itself, overwhelm persons devoted to the contemplation of one particular object. Intense and abstruse thought, in general, if not checked in time, may be attended with stu-

por or infanity.

To enable us to reflect feriously upon an important subject, time and place ought to be so chosen that the mind may be diverted by no other object; for two ideas cannot be conceived at one time. Hence we should study in an apartment which is not too light, and where we are undisturbed by noise:the mufcles should not be actively employed during study: it is therefore improper and pernicious, immediately after meals, or before digestion be completed. The morning, indeed, is the most profitable time for study; though necessity and custom make many exceptions; fo that fome perfons, from gradual practice, are able to perform their mental tasks during the greatest noise, and in a room full of children.

Much and frequent inactivity of mind agrees, indeed, well with the body, which in that state fully performs its functions, but it becomes unwieldy, infomuch as at length to stupify the mental powers: the ideas become obscure and confused; and a total loss of memory, or oblivion of the past, is but too often the consequent effect of such indolence.

CHAP. VI.

Of Sleeping and Waking: their just proportion with regard to age, the constitution of the body, mode of life, and other circumstances.

SLEEP and wakefulness are nearly in the fame relation to each other as exercise and rest. Waking always presupposes a certain degree of activity; all the natural functions, digestion, the preparation of the chyle and blood, assimilation, secretion and excretion, are then more vigorously performed, and would foon exhaust their powers, if sleep did not restore to them the beneficial and indispensable supplies.

Sleep is therefore necessary to existence and health, and it is an improper and fruitless attempt, to deprive ourselves, by an ill-directed activity, of the requisite portion of this refreshment; for Nature will maintain her rights, in spite of our efforts to subvert them: and both body and mind suffer, without attaining any real advantage from an extrava-

gant watchfulnefs.

Before I proceed to inquire into the confequences arising from either too much or too little sleep, it will be useful to premise a concise theory, or the physiology of this suspen-

fion of the mental powers.

When the body is fatigued, when the fenfes, together with the voluntary motions of the muscles, have been for some time active, we stand in need of the alternation of rest, which is obtained by fleep. During a found sleep, the senses, and the voluntary muscular motions, are not exercised; but the vital functions, such as respiration, and the circulation of the blood, as well as most of the natural functions aforementioned, are regularly though more flowly performed. During fleep, therefore, the motion of the heart and the blood-vessels, even the action of the brain and the nervous fystem, as likewise the peristaltic or vermicular motion of the stomach and the intestines, and the secretion of the sluids, are performed in an uniform and steady manner. Previous to fleep, we perceive a languor of the fenses, and of the muscles which are subject to our will, and of those also which keep the body in an erect posture; the head inclines downwards, the upper eye-lid and the lower jaw-bone likewise fink, the venous blood accumulates towards the heart, and compels us to yawn, in order to facilitate the transition of the blood into the lungs, by the deep breathing which takes place: finally, the brain itself, as the organ of the mind, appears to be fatigued; hence our ideas become irregular, and there arises a kind of faint imbecility of the understanding. That the motions of the heart are stronger during sleep, and that per-fpiration is more active, must be ascribed to the warmth of the bed-clothes, by which the infensible perspiration softens and relaxes the Ikin. But a person, who sleeps in his usual drefs, will feel chilly; and those animals that fleep long, as the hedge-hog, the murmur-deer

(Marmota Alpina, L.) suffer an extraordinary

degree of cold.

As the fenses are inactive during sleep; as the nervous energy is less exhausted, and its fecretion continued, a new fupply of it is collected, and the organs of fense, as well as the muscles, receive additional vigour. This occasions us to awake, particularly if roused by any stimulus. While we are asleep, the nutritive particles can more eafily attach themselves to the sibres, and fat also is more readily generated, from the retarded circulation of the blood. After we have flept fufficiently, we are apt, on awaking, to stretch the limbs and joints of the body, and fometimes to yawn: the latter, with an inflinctive defire of promoting the circulation of blood through the lungs, which was retarded during fleep; the former, namely stretching, in order to affift the extensor muscles, which, by the flexion of the limbs in fleep, had been more extended, and in order to expand again the flexor muscles, that had been moderately con-

The proximate cause of sleep appears to be an impeded motion of the nervous sluid in the brain. This motion is produced by a kind of collapse of the subtle insertions of the nerves, as well as by a mechanical compression of them. Hence we can explain, how things so totally opposite are able to produce sleep, when they either exhaust or compress the tubes of the nerves. Of the former kind is every violent and satiguing species of labour, a considerable loss of blood, perspiration

increased by external heat, and every thing that withdraws the blood from the head; for instance, warm baths of the lower extremities, a stomach filled with much food, &c. Of the latter kind of incitements to fleep, namely, those that act by compression, is every mechanical pressure on the brain, whether it proceed from water accumulated in its ventricles, from a local depression or fracture of the cranium, or from extravalated blood:—in like manner, the impeded regress of the blood from the brain, or the increased access of it to that organ, may effect such a pressure, by distending the blood-vessels, as is the case in using narcotics, or wine and other spirituous liquors; and, lastly, an intense degree of cold, as well as the state of an approaching apoplexy. Sleep is promoted by tranquillity of mind; by the absence of every stimulus to the body; by silence and darkness around us; by a complete rest of the fenses; by gently and uniformly affecting one of the fenses, for instance, by music or reading; and, lastly, by a gentle external motion of the whole body, as by rocking or failing. On the other hand, every painful sensation, a great noise, a bright light, strong exertions of mental powers, and particularly violent paffions, are calculated to prevent fleep. Thus likewise sleep may be impeded by hot, spicy, and other kinds of drink, which are faid to occasion a more speedy secretion of the neryous fluid.

Dreams are vagaries of the imagination, and in most instances proceed from external sen-

fations. They take place only, when our fleep is unfound, in which cafe the brain and nervous fystem are capable of performing the motions above described. We seldom dream during the first hours of sleep; perhaps, because the nervous fluid is then too much exhausted; but dreams rather occur towards the morning, when this fluid has been, in foine measure, restored. Every thing capable of interrupting the tranquillity of mind and body, may produce dreams. Such are the various kinds of grief and forrow, exertions of the mind, affections and passions, crude and undigested food, a hard and inconvenient posture of the body. Those ideas which have lately occupied our mind, or made a lively impression upon us, generally constitute the principal subject of a dream, and more or less employ our imagination, when we are afleep. Animals are likewise apt to dream, but seldom; and even men living temperately, and enjoying a perfect state of health, are seldom disturbed with this play of the fancy. Nay, there are examples of lively and spirited perfons who never dream. The great physiologist, Haller, considers dreaming as a symptom of disease, or as a stimulating cause, by which the perfect tranquillity of the fenforium is interrupted. Hence, that fleep is the most refreshing, which is undisturbed by dreams, or, at least, when we have no clear recollection of them.

I have before observed, that most of our dreams are sports of fancy, and derive their origin chiefly from external impressions: al-

most every thing we see and hear, when awake, leads our imagination to collateral notions or representations, which, in a manner spontaneously, and without the least effort, affociate with external fensations. The place where a person whom we love formerly refided, a drefs fimilar to that which we have feen her wear, the objects that employed her attention, no fooner catch our eye, than she immediately occupies our mind. And, though these images, associating with external fensations, do not arrive at complete consciousness, within the power of imagination, yet even in their latent state they may become very strong and permanent. I have been informed, for instance, of a young man, who was attacked with convulsions, every time he heard the name of Jesus repeated; owing, it feems, to the circumstance of his mother having once invoked the name of Jesus in a terrific voice and manner, when the, as well as the boy, were much frightened by a tremendous peal of thunder. But this is only an indirect demonstration of the existence of a faculty, which is very active in dreams, and which may be aptly called the fubreafoning faculty, or the power of abstracting similarities. The conclusions, thus formed, are more frequent and active, than in the waking state; because they are seldom controlled by the reflections of reason. I shall make use of one illustration only.

Very frequently we find, that in a dream a feries of reprefentations is fuddenly interrupted, and another feries of a very different kind

occupies its place. This happens, as foon as an idea affociates itself; which, from whatever cause, is more interesting than that immediately preceding. It then becomes the prevailing one, and determines the affociation. Yet by this, too, the imagination is frequently re-conducted to the former feries. The interruption in the course of the preceding occurrences is remarked, and the power of alftracting fimilarities is in fearch of the cause of this irregularity. Hence, in fuch cafee, there usually happens some unfortunate event or other, which occasions the interruption of the story. The representing power may suddenly again conduct us to another feries of ideas, and thus the imagination may be led by the fubreafoning power before defined, from one scene to another. Of this kind, for instance, is the following remarkable dream, as related and explained in the words of Prof. MAASS, of Halle: "I dreamed once," fays he, "that the Pope visited me. He commanded me to open my desk, and he carefully examined all the papers it contained. While he was thus employed, a very sparkling diamond fell out of his triple crown into my desk, of which, however, neither of us took any notice. As foon as the Pope had withdrawn, I retired to bed, but was foon obliged to rife, on account of a thick fmoke, the cause of which I had yet to learn. Upon examination, I discovered, that the diamond had set fire to the papers in my defk, and burnt them to affice."

This dream deserves a short analysis, on account of the peculiar circumstances which occasioned it. "On the preceding evening," fays Prof. Maas, "I was visited by a friend, with whom I had a lively conversation upon Joseph II.'s suppression of monasteries and convents. With this idea, though I did not become conscious of it in the dream, was associated the visit which the Pope publickly paid the Emperor Joseph at Vienna, in consequence of the measures taken against the clergy; and with this again was combined, however faintly, the representation of the visit, which had been paid me by my friend. These two events were, by the fubreafoning faculty, compounded into one, according to the ef-tablished rule—that things which agree in their parts, do also correspond as to the whole;—hence the Pope's visit was changed into a visit made to me. The subreasoning faculty, then, in order to account for this extraordinary visit, fixed upon that which was the most important object in my room, namely, the desk, or rather the papers locked up in it. That a diamond fell out of the triple crown, was a collateral affociation, which was owing merely to the representa-tion of the desk. Some days before, when opening the desk, I had broken the glass of my watch, which I held in my hand, fo that the glass fell among the papers. Hence no farther attention was paid to the diamond, being a representation of a collateral series of things. But afterwards, the representation of the sparkling stone was again excited, and

Aa2

became the prevailing idea; hence it determined the fucceeding affociation. On account of its fimilarity, it excited the reprefentation of fire, and was indeed confounded with it. Hence arose fire and smoke. But, in the event, the writings only were burnt, not the desk itself; to which, being of comparatively less value, the attention was not at all directed."

It is farther undeniable, that there are in the human mind certain obscure representations, and that it is of great advantage to be convinced of the reality of these images, if defirous of perceiving the connexion fubfifting among the operations of the imagination. Of the numerous phenomena, founded on obscure ideas, and which consequently prove their existence, I shall only remark the following. It is a well known fact, that many dreams originate in the impressions made on the body during fleep; that they confift of analogous images, or fuch as are affociated with fenfations that would arise from these impressions during a waking state. Hence, for instance, if our legs are placed in a perpendicular posture, we are often terrified by a dream, that implies the imminent danger of falling from a steep rock or precipice. The foul must represent to itself these external impressions in a lively manner, otherwise no ideal picture could be thus excited. But, as we do not become at all confcious of them, they are but faintly and obscurely represented.

If we make a resolution of rising carlier in the morning than usual; and if we imprint this determination on our mind, immediately before going to bed, we are almost certain to succeed. Now it is self-evident, that this success cannot be ascribed to the efforts of the body, but altogether to the mind; which probably during sleep perceives and computes the duration of time, so that it makes an impression on the body, whereby we are enabled to awake at an appointed hour. Yet all this takes place, without our consciousness, and

the representations remain obscure.

Many productions of art are so complicated, that a variety of simple conceptions are requisite to lay the foundation of them; yet the artist is almost entirely unconscious of these individual notions. Thus, a person performs a piece of music, without being obliged to reflect, in a conscious manner, on the fignification of the notes, their value, and the order of the fingers he must observe; nay even without clearly distinguishing the strings of the harp, or the keys of the harpfichord.-We cannot attribute this to the mechanism of the body, which might gradually accustom itfelf to the accurate placing of the fingers.— This could be applied only where we play a piece of music, frequently practifed; but it is totally inapplicable to a new piece, which is played by the professor with equal facility, though he has never feen it before. In the latter case, there must necessarily arise an ideal representation, or an act of judgment, previous to every motion of the fingers.

These arguments, I hope, sufficiently evince the occurrence of such obscure notions and

representations, as lay the ground-work of all our dreams. That among the thousands and millions of fanciful and supposed ominous dreams, some are occasionally realized, is not a matter of astonishment; but many people, particularly the victims of the lottery, too frequently find reason to regret, that these omens are not always to be depended upon; if those deluded visionaries would permit themselves to reason, and to calculate, they would discover, that there are as many chances against their dream being realized, as there are against their ticket turning up a twenty

thousand pounds prize.

Before I quit this subject, I shall relate an extraordinary dream of the celebrated Italian, GALILEO. When this great man, at a very advanced age, had loft the use of his eyes, he was once conducted in his walks over a beautiful plain, by his pupil, TORICELLI. "Once," faid the aged fage, " my eyes permitted me to enjoy the charms of these fields. But now, fince their light is extinguished, these pleafures are lost to me for ever. Heaven justly inflicts the punishment which was predicted to me many years ago. When in prison, and impatiently languishing for liberty, I began to be discontented with the ways of Providence; Copernicus appeared to me in a dream; his celestial spirit conducted me over luminous stars, and, in a threatening voice, reprehended me for having murmured against him, at whose fiat all these worlds had proceeded from nothing. "" A time shall come," faid he, "when thine eyes shall refuse to asfift thee in contemplating these wonders."

After this long, though I hope not uninteresting digression, I proceed to state the consequences arising from too much or too little

fleep.

To continue in a waking state, beyond a proper time, confumes the vital spirits, disorganizes the nerves, and causes so many uncafy fensations, that a considerable while must elapse, before we can fall asleep, namely, until their greatest violence has abated. The fluids of the body become acrid, the fat is confumed, and there arifes at length an inclination to vertigo, violent head-ach, anxiety, actions without connexion, without design, and without confiftency. Thefe who indulgs themselves in much sleep, are seldom liable to very strong passions. Persons, on the contrary, who fleep too little, frequently contract a violent and vindictive temper. Longcontinued wakefulness is capable of changing the temper and disposition of mind of the most mild and gentle; of affecting a complete alteration of their features, and, at length, of occasioning the most singular whims, the Arangest deviations in the power of imagination, and, in the end, absolute infanity.

Excess of sleep, however, is not less prejudicial. The whole body sinks gradually under a complete state of inactivity, the solid parts become relaxed, the blood circulates slowly, and remains particularly long in the head: perspiration is disordered, the sluids are incrassated, the body increases in fat and thick humours, and is rendered incapable of being the medium of mental exertion, the

memory is enfeebled, and the unhappy fleeper falls into a thoughtless lethargic state, by which his fensibility is, in a great measure, destroyed.

Perfons troubled with hypochondrialis and hyfterics do themselves much injury by fleeping too long, especially in the morning, when the body is much weakened by its too long continuance in a heated and unwholefome atmosphere. To fuch individuals, it is also dangerous to remain for a length of time in a flate of inactivity. Indeed, excess in fleeping is detrimental to the muscular powers of every person; to the phlegmatic, especially, whose fluids will thus foon be univerfally corrupted; and fanguine temperaments thereby acquire a superabundance of blood. The melancholy, whose blood circulates flowly, must suffer inconveniencies in their secretions and excretions by this indulgence; and we generally find, that long fleepers are afflicted with costiveness and obstructions .-Early rifing, and timely going to bed, may alone render them more healthy and vigorous.

If it can be advantageous to any description of persons, to sleep beyond the usual portion of time, it is to the choleric. To sleep immediately after supper, is apt to occasion the night-mare, or a stagnation of the blood, which, by its pressure, produces the sensation or idea of this troublesome bed-fellow. It is principally the nervous, the debilitated, and those of an impaired digestion, who are visit-

ed by fuch terrifying dreams.

The proper duration of sleep, in youth and adults, is usually settled at six or seven hours; in children and the aged, from eight to nine hours. Yet the individual deviations in the constitution of the body, and its various wants, scarcely admit of any accurate rules. The more bodily weakness we feel, the more we may indulge in sleep, provided it be refreshing. If people in a state of health are perfectly cheerful in mind and body, when they sirst awake, this is the most certain criterion, that they have slept sufficiently.

We should, however, be on our guard, not to confound the natural wants of the body with a blameable custom. For most persons habitually fleep too much, or remain longer in bed than they ought. The principal cause of this destructive custom undoubtedly arises in infancy; when children are permitted to fleep in very foft and heating beds, and encouraged to lie longer than is proper, from a mistaken notion that they cannot sleep too much. From this injudicious treatment, they cannot attain a folid texture of the body, and a foundation is laid for many subsequent discases. The rickets, so very common in many families, in the prefent age, often originate in fuch indulgencies, finee the general relaxation of the body, and the tendency to profuse perfpiration, is thus promoted in an extraordinary degree. At the age of puberty, this effeminacy of the body, and the inclination to fleep, together with the pleafant fenfation, which a foft and warm bed affords in a waking state, are certainly the first and most frequent causes of a vice, that might be effectual-

ly prevented by early rising.

The custom of sleeping long, when continued to the state of manhood, becomes so habitual that it cannot be relinquished without great struggles, and a firm resolution. Those, then, who are not possessed of this firmness, instead of attaining a strong constitution, will acquire a phlegmatic, relaxed, and cold temperament, which will render them irresolute, and incapable of energetic efforts; and from which the mind, by degrees, becomes as indifferent towards every object, as the body is unfit for mufcular exertion.— Hence, to listen to the voice of Nature, in this respect, will contribute more to our happiness, than to shorten our repose by many of the usual but violent means of excitement, when the body is in want of rest.

To children, at a very early period of life, no limits of fleep can be prescribed; but, after the fixth or seventh year of age, some regulations become necessary, to habituate them to a certain regularity. The just proportion of sleep can be ascertained only, by their more or less lively temperament, by their employments, exercise and amusements through the day, and according to the more or less healthy state of their bodies. In pursuing this measure, however, we must not attempt to awaken children from their sleep, in a violent or terrifying manner, which is frequently done, and

is extremely pernicious.

In great disquietude of mind, and after violent passions, sleep is the more necessary, as

these agitate and exhaust the frame, more than the most fatiguing bodily labour. Hence, many persons never sleep so sound, as when they are afflicted with grief and forrow. A fretful and peevish temper, as well as a sit of the hypochondriasis, cannot be more effectually relieved, than by a short sleep. Frequently, after a sleep, of a sew minutes only, we awake refreshed, we can reslect on our difficulties with a calm mind, and again reconcile ourselves to the troubles of life. In such situations, though we should not be able to sleep, even a quiet posture of the body, with

the eyes closed, is of fome advantage.

There is fearcely any misfortune fo great, that it cannot be relieved or alleviated by fleep; as, on the contrary, we should inevitably sink under its pressure, if this beneficent balm did not support us. Yet, frequently too, uneafiness of mind, by its continual stimulus on the censorium, prevents all sleep: hence the unquiet repose and even whole sleepless nights of those, whose heads are filled with cares or important schemes. As mental labours exhauft our strength more than those of the body, literary men, who employ themselves in long and profound reflections, require more fleep than others. Though fome perfons, whose body and mind are equally indolent, have a greater inclination to fleep, than the lively and laborious, yet it is not so beneficial to them; fince they are destitute of the effential requifites to health, namely, activity and vigour. Bb

The most healthy, and those who lead the most regular lives, frequently have an uneasy and very short sleep: they also require less rest at one time than another. He who digests easily, stands less in need of sleep than others. After taking aliment difficult of digestion, Nature herself invites to the enjoyment of rest, and to sleep in proportion to the time which is required for the concoction and affimilation of food.—Excessive evacuations of whatever kind, as well as intoxication by strong liquors, render additional sleep necesfary. In winter and fummer, we require fomewhat more time for fleep than in spring and autumn; because the vital spirits are less exhausted in the latter seasons, and the mass of the blood circulates more uniformly, than in the cold of winter or heat of fummer, when it is either too much retarded, or accelerated.

It is very improper to fit up too late in the long winter evenings, whether at the desk or the bottle, either of which is then more hurtful than in summer, because the want of sleep is greater. Those who wish to spend the winter in good health, and useful labour, should retire to bed at eight o'clock in the evening, and rise at three or sour o'clock in the morning. A winter morning, indeed, is not very charming, but the evening is naturally still less so; and there is no doubt, that we can perform every kind of work, with more alacrity and success, in the early part of the day than at night; and that our eyes would likewise be benefited by this regula-

tion, after fleep has enabled them to undertake any task in the morning; but they are fatigued at night, from the exertions of a

whole day.

Every stimulus may interrupt sleep, or at least render it uneasy, and often occasion dreams, the cause of which is generally owing to an irritation in the stomach, or in the intestinal canal. Dreams are, as it were, a middle state between sleeping and waking, and generally indicate some defect in the body, unless they give representations which originate in the occurrences of the preceding day.

An uneasy sleep, which is obvious from starting up, or speaking in it, and from a frequent change of the posture in bed, is at no time a good symptom; it is as frequently a forerunner, as it is the effect of disease, and

may be owing to the following causes ;

1. Emotions of the mind and violent paffions always diforder the vital spirits;—at one time they increase, at another diminish, and sometimes altogether check their influence, the consequences of which extend to the whole circulation of the blood. Sorrows and cares produce a similar effect. Hence the nocturnal couch is a very improper place to prosecute moral researches, or to recollect what we have done, spoken, and thought through the day.—To read interesting letters, received late in the evening, usually too occasions an unquiet sleep.

2. A bad state of digestion, and especially hard or corrupted food, on account of the connexion of the brain with the stomach.

3. A repelled perspiration, if we have not covered ourselves conformably to the climate, season, and weather.—In this case, a current of air is still more hurtful than intense cold.

4. An apartment or bed to which we are not accustomed may also occasion an uncomfortable sleep, as travellers frequently experience. It is therefore an effential part of a good and healthful education, to accustom children to sleep alternately upon different, and harder or softer couches, in various parts of the house, more or less temperate, which consequently enables them to sleep comfortably in a simple but clean bed, in whatever

place or fituation they may find it.

Debilitated perfons injure themselves much by sleeping during the day, against the order of Nature, and keeping awake the greater part of the night. Day-light is best adapted to astive employments; and the gloom and stillness of the night to repose. The evening-air which we inhale soon after fun-set, and nightair in general, which is vitiated in the country by the exhalations of plants, is very detrimental to the delicate. The forced watchfulness of those who apply themselves in the night to mental pursuits, is exceedingly prejudicial. A couple of hours sleep before midnight is, according to old experience, more refreshing than double the quantity after that period.

The question, whether to fleep after dinner be advisable, must be decided by a variety of concurrent circumstances; custom, bodily con-

flitution, age, climate, and the like.

In a weak and flow state of digestion, after having taken hard or solid food, we may indulge ourselves in a short sleep, rather than after a meal consisting of such nourishment, as by its nature is easily concocted. But debilitated young people especially should not sleep too much, though their weakness incline them to it; for the more they indulge in it, the greater will be their subsequent languor and relaxation.

Individuals of a vigorous and quick concoction may undertake gentle, but not violent exercife, immediately after meals, if they have eaten food that is easily digestible, and which requires little assistance, but that of the stomach and its stuids. And even such persons, if they have made use of provisions dissicult to be concocted, ought to remain quiet after dinner, and may occasionally allow themselves half an hour's sleep, in order to support di-

gestion.

To rest a little after dimer, is farther useful to dry and emaciated persons, to the aged, and persons of an irascible disposition; to those who have spent the preceding night uneasily and sleepless, or have been otherwise fatigued, in order to restore regularity in the insensible perspiration; but in this case the body must be well covered, that it may not be exposed to cold. Such as are fond of sleeping at any time of the day, are usually more indolent and heavy after it than before. A sleep after dinner ought never to exceed one hour; and it is also much better sitting than lying horizontally; for, in the latter case, we

B b 2

are more subject to fluctuations of the blood towards the head, and consequently to headach.

Much depends upon the manner of lying in bed, and on the posture to which we accustom ourselves. To lie on the back, with the arms over the head, prevents the circulation of the blood to the arms, and is not unfrequently productive of serious consequences. It is equally pernicious to lie in a crooked posture, or with the breast very low and bent inwards; for the intestines are thereby compressed and obstructed in their motions, and the blood cannot eafily circulate downwards; whence may arife giddiness and even apoplexy. Lying on the back is equally improper, and produces frightful dreams, together with many other inconveniencies; the reverse posture is likewise noxious, as the stomach is thus violently oppressed, the free respiration much impeded, and the whole circulation of the fluids in the cheft and abdomen wantonly prevented, to the great injury of health.

The most proper posture, then, is on one side, with the body straight, the limbs slightly bent (not stretched, because they ought to rest) so that the body may lie somewhat higher than the legs. When the head is laid high, a short sleep is more refreshing than a longer one when it is reclined too low. To healthy people it is a matter of no consequence on which side they lie, and they may safely, in this respect, sollow their own choice. Some dietetical observers allege, that it is better to lie in the evening on the right, and in the

morning on the left side; that in the evening the food may more readily leave the stomach, and that afterwards this organ may be

better warmed by the liver.

In the evening we should eat light food only, and that sparingly, wait for its digestion, and consequently not lie down till two or three hours after supper. The mind ought to be kept quiet and cheerful, previous to going to rest: we should then, as much as possible, avoid gloomy thoughts, which require reslection and exertion. It is therefore a pernicious and dangerous practice to read ourselves assept in bed. We would do much better, to exercise ourselves a little before bed time, by walking up and down the room.

Sleep without dreams, of whatever nature they may be, is more healthful than when attended with these fancies. Yet dreams of an agreeable kind promote the free circulation of the blood, the better concoction of food, and a due state of perspiration. The contrary takes place in unpleasant dreams, which excite anxiety, terror, grief, fear, and the like. In the latter case, they are of themselves symptoms of irregularity in the fystem, of an approaching disorder, or of an improper posture of the body. The functions of the body before mentioned are impeded by fuch dreams; and the vital spirits, which ought to be reflored and cherished, are again dissipated by violent emotions, insomuch that the body and the mind continue unrefreshed.

In order to preserve the body warm, we make use of feather-beds and covers:—in

fummer, at least, we ought to fleep upon mattresses. It is a most essential requisite to every person, who wishes to lead an agreeable, active, and useful life, to provide himself in time with a proper couch. To insure all the advantages which may be derived from this quarter, nothing is better than a mattress filled with horse-hair, or, if cheapness be an object, with dry moss, at least six inches thick. Several of fuch mattreffes may be placed one above another; the bolfter ought to be well stuffed and elastic; in winter with feathers, and during the fummer with horse-hair, more or less high, according to circumstances, but always fo that the head may lie confiderably more elevated than the breast and the rest of

the body.

The cover should never be tucked in too closely, that the access of external air may not be altogether excluded. If we make use of a bedftead or a fofa provided with fteel fprings, one of the mattreffes above described, with a fimilar bolfter, and the light cover of a double blanket, will be found fufficient. These beds are not only the most convenient for early rifers, but also the most conducive to health. The higher classes of fociety in Ireland appear to be fo well convinced of the falubrity of this mode of fleeping, that their children, instead of being placed on enervating feather-beds, are habituated to fleep upon bags filled with cut straw, with blankets laid over the bags for foftness, and but slightly covered. I understand, that this praise-worthy practice is every day becoming more general.

indeed, there is no doubt that the muscles and nerves are more braced by a proper elaftic couch, than either by the most exquisite down of Norway, or the most powerful tonic or strengthening remedies taken internally. Yet these remarks are applicable only to the healthy state of the body, when Nature requires no additional aid or precaution, in managing the organs of perspiration.—Every bed ought to be so regulated, that it may flope down imperceptibly towards the feet; and if the particulars before stated be attended to, a healthy person will never sleep too long: he will generally awake in fix hours, feel himself refreshed, rise with cheerfulness, and be fit to undertake any exertions, either

of body or mind.

What has been remarked in a former Chapter on Drefs, and the advantages derived from covering the skin with animal wool, particularly in enervated and infirm people, is likewise applicable here, with respect to the dress, and the immediate covering of the skin, when in bed. Though we usually undress ourselves as far as the shirt, partly for the sake of cleanliness, and partly with the view of relieving the body from every pressure and in-cumbrance, and of promoting a free circulation of the blood; yet we should be cautious, lest we materially hurt ourselves by a sudden exposure to the air, when undressing, especially after the hot and fultry days of fummer. A long and commodious night-gown of flannel would be a proper night drefs; especially for those who retire to their bed immediately after the bath, in order to preserve a gentle

degree of perspiration.

The head should not be covered with a warm stannel or worsted night-cap, as it were to make it a vapour-bath; the thinnest cotton or linen cap being fully sufficient. The consequences resulting from the pernicious practice of keeping the head too warm, have been explained on a former occasion. The shirt-collar should be loose, the wristbands open; and if from a bad habit we have been accustomed to wear neckcloths during sleep, they should be tied as loosely as possible. Persons who are naturally chilly in the lower extremities, or are liable to pains of the stomach and abdomen, would do well to sleep in woollen stockings, but not in the same which they

have worn through the day.

The feather-beds, in which we usually sleep, are certainly hurtful in many diseases, some of which they may even produce. For they abforb or imbibe the perspired vapours thrown out of the body, without our being able to cleanse them of these impurities, which are again re-absorbed and re-conducted through the pores, to the great injury of health. For this reason, mattresses filled with horse-hair, or moss, are in every respect preserable. But, as many individuals have not fufficient resolution to use these, or are apprehensive of the consequences attending a sudden change, they may at least cause their feather-beds to be frequently and carefully shaken, aired in the sun, and provided with a new covering. For the same reason, the bed ought not to be made immediately after rifing, as is generally practifed; but the clothes should be taken off, spread out, and not laid on the bed, until the time of going to rest draws near. Farther, it is highly improper to sleep in beds overloaded with clothes: they heat the blood more than is consistent with health, and produce an immoderate and enervating perfpiration, which still more weakens the organs

already relaxed by fleep.

The custom of sleeping with the curtains drawn close, is pernicious to health, because the copious exhalations which then take place, cannot be properly dissipated, and are consequently again absorbed. It is also imprudent to hide the head almost entirely under the bed-clothes. Persons who cannot sleep without curtains, should tuck up the lower ends of them, or place them over chairs, so that they may not lie close to the bed, but admit a more free access of air; that side alone, which is next the wall, ought to be entirely covered with the curtain.

For fimilar reasons, the large common fleeping halls, or wards in public schools, as well as in hospitals, are extremely prejudicial to health; though they may be necessary evils, and cannot be easily remedied in the great seminaries of education. Neither the most healthy situation, with high, losty, and spacious apartments; nor the daily practice of airing and cleaning them, are sufficient to counteract the bad essentials from this baneful custom of crowding so many persons together to breathe in a common and consined atmosphere.

From these considerations, as well as in many other respects, the sleeping together in one bed, whether children or adults, is at best a disgusting and immoral custom; besides the positive disadvantages it has with respect to health. Unless poverty or necessity render this custom unavoidable, it ought not to be practised, either among married or other persons, and still less among children. It has been remarked, even in the domestic economy of barbarous nations, that, in general, ev-

ery individual has a feparate couch.

The old custom of warming the bid also deserves to be condemned; as it has a direct tendency to produce weakness and debility. This will be still more dangerous, if it be done with a charcoal sire, which, by its poisonous vapours, may prove very pernicious. A person who is accustomed to sleep in a cold bed, will not seel much inconvenience in the severest cold; for, after being a short time in bed, the natural warmth of the body will overcome it: as, on the contrary, those who sleep in a warmed bed, will be the more liable to seel cold, as soon as this artiscial heat is dissipated.

If it can be avoided, the bed-room ought not to be on the ground floor, nor towards the North. Many people prefer this fituation in fummer, on account of the cool air; they should, however, consider that, in such an apartment, the morning as well as the nightair, is damp and unwholesome. A bed-chamber ought to be exposed to the early rays of the sun, which awake man in a state of health

at a proper time, and enliven, strengthen, and incite him to leave the bed, after having been refreshed by rest. It is, farther, more advisable to endure a moderate degree of heat, which may be modified at pleasure, by various means, than to inhabit damp and low-situated apartments, from which the moisture

cannot be easily dried up in summer.

A fpacious and lofty room should always be chosen for a bed-chamber; for small closets and, above all, concealed beds are extremely objectionable.-The windows should never be left open at night; and as damp rooms are very prejudicial to health, we ought to pay particular attention, that the bed may not be placed near a damp wall. It is in every case preferable to place the bed so, that all the fides of it stand free. This method of placing the bedflead, in or about the middle of the room, has another advantage which, with timorous persons, is perhaps of importance. It it well known, that a flash of lightning, if it accidentally enter through a window, will take its direction along the walls, and not touch any thing placed in the middle of a room.

Lastly, no candle or rush-light should be kept burning during the night in a bed-room; for it not only vitiates the air in a very considerable degree, but it disturbs and prevents the rest of those whose sleep is uneasy, particularly the aged. In a dark apartment, sleep generally comes without much invitation;

as, on the other hand, the light of a candle flimulates the brain, consequently the whole nervous system; and the approaching comforter, whose arrival we so fondly wish, is thereby prevented, or easily interrupted, and banished to calmer regions.

FND OF THE FIRST VOLUME.

ADVERTISEMENT TO THE FIRST EDITION.

THESE Lectures, with the exception of the Eighth and Ninth Chapters, were delivered last winter* at Bath, and in the spring at Bristol, to numerous and respectable audiences. The Author had no intention, at that time, to publish them; but as he found no Work, in the English language, comprehending such a fystematic view of the various and important objects which came more immediately under his confideration, and conceived that the diffemination of the rules selected by him might be generally useful, he was induced to alter his refolution, and submit them to the candour of the Public.

To many English and German writers he must acknowledge his obligations, in the composition of his Work. Among the former, he has occasionally availed himself of the excellent Writings of PRIESTLEY, on the subject of · Air and Weather; of FotherGILL and VAUGHAN, on · Drefs; and of Armstrong, Cullen, and Falconer, on ' Food and Drink? To Dr. FOTHERGILL also, on the fubject of ' Sleeping and Waking,' he is much indebted, as well as to Mr. Adams's useful Treatise on the ' Treat-

ment and Preservation of the Eyes.'

Beside the valuable observations drawn from all these fources, he has been greatly affifted by the opinions of feveral German writers, viz. Ingenhouz, Hahnemann, HUFELAND, MARCARD, SEMMERING, UNZER, ZIMMER-MANN, and others; having derived confiderable advantage from the general result of their respective inquiries on the subject of Diet and Regimen.

Although it can scarcely be expected that a Work of this nature should be perfect, or free from inaccuracy, the Author has spared no pains to render it deferving of the public favour, and trusts it will be found a domestic guide

both to families and individuals.

Should the rules and cautions, interspersed throughout, tend, in the smallest degree, to increase the knowledge of the inquisitive, diffuade the unwary from injurious habits, or rescue the sensualist from the brink of destruction, the exertions of the Author will be amply compensated.

In the months of January and February, 1798.

TO THE SECOND LONDON EDITION.

THE first Edition of these Lectures having met with a degree of approbation beyond the most sarguine hopes of the Author, he has testified his grateful sense to a discerning Public, not only by correcting and improving every page of the Work, but likewise by enlarging and rendering it as complete as the limits of a single volume would admit.

Many important and useful articles have been added, especially in the Fifth Chapter, "Of Food and Denk." The principal new subjects the Reader will, on consulting the Alphabetical Index, find under the terms—Arrow-root—Artichokes—Asparagus—Barley—Beans—Beet-root—Cow-pox—Consamption—Exercise—Figs—Game—Lob-sters—Manna-grass—Metallic Tradors—Millet—Oats—Oil—Olives—Parsnips—Rice—Sago—Salfasy—Salt—Skirret-root—Small-pox—Tamarinds—Vincgar, &c. &c.

The quotations translated from Dr. Mead's "Medical Precepts," and inferted in the conclusion of these Lectures, will be deemed interesting by every resecting mind.

To this edition the Author has added a "Puffeript," to which he refers the Reader with respect to the limited design of the present book, and the practical tendency of a new work, "On the Dietetic Treatment and Cure of Diseases;" which will contain the fatther application of these Lectures in a diseased state of the body.

With this view, he has thought proper to subjoin a series of Queries, addressed to those patients who are anxious to give an accurate and suisfactory account of their disorder, when consulting medical men, especially if they

cannot have the benefit of an interview.
